### The Thick and Thin of Meningeal Carcinomatosis

The case report by Kim et al. [1] in the March/April 1980 *AJNR* describing meningeal carcinomatosis claims that "this form of metastasis has not been previously reported."

A comprehensive review article on the subject that involved 50 patients with meningeal carcinomatosis was published 6 years ago [2]. In that article, seven of 18 patients underwent myelography and showed multiple nodular defects including concentric narrowing of the subarachnoid space.

The article to which Dr. Kishore refers reviews infiltration of leptomeninges by systemic cancer, not infiltration of the meninges or certainly not pachymeninges.

In our introduction, we said that there were four types of metastases in the spine: (1) epidural; (2) intradural (nodular form); (3) leptomeningeal carcinomatosis (diffuse sheetlike infiltration of the pia-arachnoid); and (4) pachymeningeal carcinomatosis (diffuse sheetlike infiltration of the pachymeninges).

The article mentioned by Dr. Kishore refers to cases in category 3 and possibly category 4. We have experienced two cases of pure leptomeningeal carcinomatosis in the lumbar region (lymphomatous and leukemic infiltration). We believe that the myelographic features of each category are distinct from one another. We are still unable to find any previous report of spinal pachymeningeal carcinomatosis.
