MR of Myelomatous Meningitis

Douglas J. Quint, Richard Levy, and John C. Krauss

Summary: In a 56-year-old woman with multiple myeloma involving the leptomeninges diffusely, MR of the spine showed multiple vertebral compression fractures and marked enhancement of the cauda equina region. Intracranial MR showed pathologic enhancement of the left third and fifth cranial nerves.

Index terms: Multiple myeloma; Meningitis

Central nervous system involvement by multiple myeloma can present as either a mass or a diffuse leptomeningeal process. We present a case of diffuse spinal canal leptomeningeal myelomatosis demonstrated on contrast-enhanced magnetic resonance (MR) imaging.

Case Report

A 56 year old woman presented to the emergency room with a 1-week history of progressive bilateral lower extremity pain and weakness. She had a 7-year history of multiple myeloma (complicated by multiple thoracolumbar vertebral compression fractures), which had been successfully managed on an outpatient basis with occasional courses of melphalan/prednisone or cyclophosphamide/prednisone chemotherapy.

Physical examination revealed lower-extremity paraparesis and decreased rectal tone. Spine MR demonstrated multiple vertebral compression fractures (that had been demonstrated on previous plain radiographs) and marked enhancement of the cauda equina region (Fig 1). Subsequent lumbar puncture revealed plasma cells. This combination of findings was considered consistent with myelomatous meningitis. Intracranial MR demonstrated pathologic enhancement of the left third and fifth cranial nerves, also consistent with meningeal spread of myeloma.

Radiation therapy, intrathecal methotrexate, and prednisone therapy were instituted, but had to be stopped because of myelosuppression. The patient rapidly deteriorated and died 3 weeks after cessation of therapy.

Discussion

Involvement of the central nervous system by multiple myeloma can be attributed to direct invasion from contiguous involved bone or can be separate from bone involvement, presumably by hematogenous spread (1). Separate central nervous system lesions are believed to occur in fewer than 1% of patients with multiple myeloma (2). Central nervous system lesions can present as either diffuse leptomeningeal involvement or, more rarely, as extraaxial masses. In 1992, Leifer (1) reviewed 34 cases from the literature and reported 3 new cases of leptomeningeal involvement by multiple myeloma.

Our patient demonstrated dramatic enhancement of the distal thecal sac, including the cauda equina nerve roots, resulting from diffuse seeding of the leptomeninges/subarachnoid space by myeloma. Such enhancement is attributable to breakdown of the blood-nerve barrier (3). Although this MR finding is sensitive with respect to the presence of an abnormality, it is relatively nonspecific for the cause of the lesion: carcinomatous meningitis (primary central nervous system, breast, melanoma, lung, etc) (4), lymphomatous meningitis, arachnoiditis (eg, postoperative or secondary to intrathecal chemotherapy), Guillain-Barré syndrome (5), sarcoidosis, or infectious processes (6) such as parasitic, tuberculous, bacterial (including Lyme disease [7]), and viral (acquired immunodeficiency syndrome-related cytomegalovirus polyradiculomyelitis [8]) infections can have a similar appearance.

Therefore, in the appropriate clinical setting, dissemination of myeloma to the leptomeninges should be added to the differential diagnosis of diffuse enhancement of intradural, extramed-

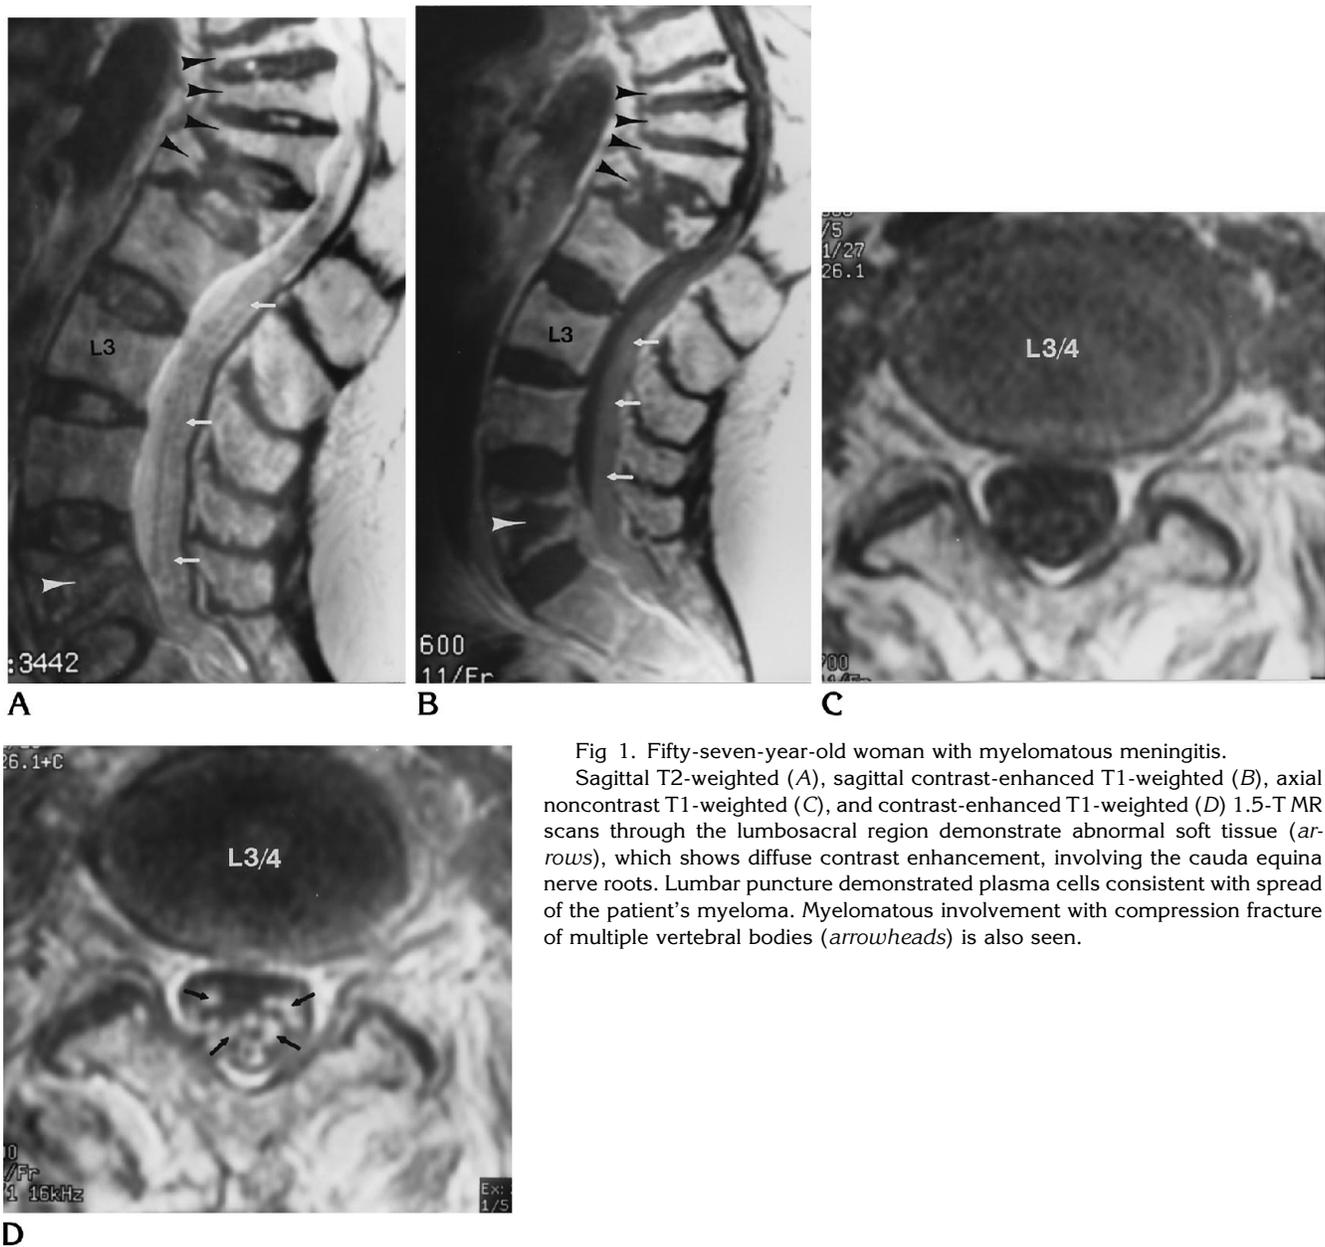

Fig 1. Fifty-seven-year-old woman with myelomatous meningitis.

Sagittal T2-weighted (A), sagittal contrast-enhanced T1-weighted (B), axial noncontrast T1-weighted (C), and contrast-enhanced T1-weighted (D) 1.5-T MR scans through the lumbosacral region demonstrate abnormal soft tissue (arrows), which shows diffuse contrast enhancement, involving the cauda equina nerve roots. Lumbar puncture demonstrated plasma cells consistent with spread of the patient's myeloma. Myelomatous involvement with compression fracture of multiple vertebral bodies (arrowheads) is also seen.

ullary structures on MR images. Cerebrospinal fluid analysis in these patients should always include studies to rule out both inflammatory/infectious processes and neoplastic processes.
