Solitary Hypothalamopituitary Toxoplasmosis Abscess in a Patient with AIDS

SUMMARY: Toxoplasmosis is a disease caused by an obligate intracellular protozoal parasite, *Toxoplasma gondii*. It is the most common cause of focal brain lesions in patients with AIDS. The imaging features and endocrine disorders of CNS toxoplasmosis in patients with AIDS are reviewed.

ABBREVIATIONS: CNS = central nervous system; FLAIR = fluid-attenuated inversion recovery; HIV = human immunodeficiency virus; PCR = polymerase chain reaction

Toxoplasmosis is the most common cause of focal brain lesions in patients with AIDS,¹ even if the number of cases has declined with the introduction of highly active antiretroviral therapy. Neuroimaging usually reveals multiple nodular or ring-enhancing lesions with edema and mass effect.² The clinical manifestations are nonspecific and depend on the location of the lesions. Focal neurologic symptoms are often superimposed on global encephalopathy. Infections of endocrine organs result in endocrine disorders. We present a unique case of solitary hypothalamopituitary toxoplasmosis abscess causing central diabetes insipidus and corticotropic insufficiency and revealing AIDS.

Case Report

A 36-year-old woman consulted us for fever and pain in the maxillary area. She was treated with amoxicillin, clavulanate potassium, and corticotherapy for 8 days for suspicion of sinusitis. Persistence of fever led to another antibiotic treatment (levofloxacin) for 9 days. Seven days later, she was admitted to the emergency department for confusion, hypothermia, and hypotension.

Unenhanced CT revealed a 15-mm area of abnormal low attenuation centered on the optic chiasm and hypothalamic region. This area demonstrated ring enhancement on postcontrast CT images. MR imaging confirmed the single character of the lesion, which was hyperintense on T2-weighted sequences and surrounded by high-signal-intensity vasogenic edema involving the optic tract, cerebral peduncles, anterior commissure, internal parts of the temporal lobes, and posterior arms of the internal capsules. The lesion was isointense on T1-weighted sequences, with an asymmetric target sign (a small eccentric nodule along the wall of the enhancing ring) on postcontrast sequences.³ The pituitary stalk was thickened (Fig 1).

A rapid screening test was positive for HIV. Examination of blood revealed lymphopenia and 8 CD4 cells/mm³. Serum toxoplasma immunoglobulin G was positive. Testing of CSF revealed no pleocytosis but elevated levels of protein, hypoglycorrhachia, and a PCR positive for *Toxoplasma gondii*.

Treatment was started, including pyrimethamine, sulfadiazine,

and folinic acid. In addition, the patient received antibiotics for 3 days on the basis of the hypothesis of pyogenic abscess.

At day 3, the patient developed polyuria and polydipsia. Natremia and plasma osmolality were high whereas urine osmolality was low. Response to vasopressin led to the diagnosis of diabetes insipidus. Endocrine testing was performed, revealing a corticotropic insufficiency, which was treated with hydrocortisone. The hypothalamothyroid axis was not disturbed. Ophthalmologic examination revealed quadrantanopia.

Control MR imaging performed 3 weeks after the beginning of the treatment demonstrated almost complete regression, with nothing but a small area of high signal intensity on T2-weighted images and a light enhancement of the hypothalamic region (Fig 2). The clinical outcome confirmed the diagnosis of CNS toxoplasmosis.

Discussion

To our knowledge, this is the first report of unique hypothalamopituitary toxoplasmosis abscess responsible for central diabetes insipidus and corticotropic insufficiency.

T gondii can infect any cell in the brain, but most lesions occur in the basal ganglia, thalamus, and corticomedullary junction. Lesions are usually multiple and are solitary in only approximately 14% of cases.³ A solitary lesion in a patient with AIDS is more likely to be a lymphoma (the second most common cause of space-occupying brain lesions in AIDS) than toxoplasmosis,⁴ and imaging appearances can be very similar. Several techniques have been suggested to help differentiate both, including diffusion-weighted imaging,⁵ MR spectroscopy, single-photon emission CT, and positron-emission tomography.² However, none of these has high specificity, and they are only useful when combined.

Also, a solitary brain abscess can be caused by other opportunistic microorganisms, such as *Mycobacterium* species, *Aspergillus* species, *Nocardia* species, *Cryptococcus neoformans*, and *Listeria monocytogenes*. Therefore, the presence of an intracranial mass in a patient with AIDS allows empiric treatment for cerebral toxoplasmosis, and failure to respond to therapy within the first 2 weeks dictates the need for a stereotactic biopsy.^{6,7} Although a definitive diagnosis of CNS toxoplasmosis relies on the identification of parasites by histopathology, the clinical and radiologic data can be complemented by a less invasive approach that confirms the presence of parasites in the CSF. In a recent study, a positive PCR as in our case has been found to have high sensitivity and specificity (83.3% and 97.5%, respectively).⁸

Opportunistic infection is one of the various pathogenic

mechanisms leading to endocrinopathies of the HIV disease.⁹ Others include neoplasms, drugs administered to treat infections, and cytokine abnormalities associated with the HIV disease process.¹⁰ There have been a few cases of diabetes insipidus,^{11–14} panhypopituitarism,¹⁵ or both¹¹ complicating CNS toxoplasmosis among patients with AIDS. In these reports, cerebral imaging findings were either normal (earlier cases^{12,13}) or showed multiple abscesses as usually described in cerebral toxoplasmosis, some involving the pituitary gland¹⁵ or the infundibulum (pituitary stalk).¹¹

Conclusions

CNS toxoplasmosis can have unusual presentations in patients with AIDS, whether it is the solitary nature of the abscess or its rare localization. When hypothalamopituitary dysfunction complicates the infection, antiparasitic medication is effective in the treatment of endocrine abnormalities.
