Image Processing to Improve Detection of Mesial Temporal Sclerosis in Adults

F. Dahi, M.S. Parsons, H.L.P. Orlowski, A. Salter, S. Dahiya, and A. Sharma

ABSTRACT

SUMMARY: In this retrospective case-control study, we investigated whether an image-processing algorithm designed to exaggerate the intensity of diseased hippocampi on FLAIR images can improve the diagnostic accuracy and interobserver reliability of radiologists in detecting mesial temporal sclerosis–related hippocampal signal alteration. Herein, we share the results of this study that showed that the image processing improved the confidence of radiologists in detecting mesial temporal sclerosis–related signal alteration, allowing an improved sensitivity, specificity, and interobserver reliability.

ABBREVIATIONS: MTS = mesial temporal sclerosis; SI = signal intensity

A confident identification of mesial temporal sclerosis (MTS) based on hippocampal volume loss, signal abnormality, and architectural distortion on MR imaging is important for timely surgical management of refractory epilepsy.^{1–4} Because signal abnormalities may precede volume loss in MTS, improved detection of hippocampal signal abnormalities may help in its early diagnosis and treatment.⁵ Recently, an image-processing algorithm using correlative properties of neighboring pixels has shown promise in selectively enhancing the visual conspicuity of diseased hippocampi.^{6,7} Here we share the results of a retrospective case-control study testing whether this image processing could translate into an improved diagnostic performance of radiologists in detecting MTS in adults.

MATERIALS AND METHODS

Image Processing and Review

A blinded coinvestigator processed coronal FLAIR images from 51 subjects with MTS and 51 healthy controls (Table 1) with a proprietary image-processing algorithm (Correlative Image Enhancement) using a custom plug-in for OsiriX Lite (https://www.downloadthat.com/windows/search/osirix_lite_for_windows).

The algorithm exaggerated the hippocampal signal intensity (SI) if it was considerably higher than that of the normal gray matter as defined by an ROI drawn over the normal-appearing insular cortex. Processed images were saved as a separate DICOM series. Six readers with varied experience levels reviewed baseline and processed images separately, rating the SI of each hippocampus on a 5-point scale: 1, definitely normal; 2, probably normal; 3, possibly normal; 4, probably abnormal; and 5, definitely abnormal. They also indicated whether the hippocampal SI was unusually high, suggesting the effect of processing.

Data Analysis

Differences among the median SI ratings across all readers for baseline and processed images were computed and compared using a paired *t* test or signed rank test. If one considered the SI ratings of 1–3 as normal and 4–5 as abnormal, the effects of processing on the sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of each reader and for all readers were assessed. Sensitivity was additionally assessed for a subgroup of patients in whom the MR imaging findings were originally reported as normal. The effect of processing on the interobserver reliability of identifying hippocampal signal abnormality (SI ratings) was computed using a model-based measure of agreement, which is robust to the underlying disease prevalence.⁸

RESULTS

All readers reported confluent areas of markedly increased signal (Fig 1) in processed images of 37 (72.5%) diseased hippocampi. Individual readers reported processing-related foci of markedly

Table 1: Details of cases and controls

	Subjects	Controls
Mean age (range) (yr)	34.6 (18–58)	42.8 (21–79)
Men	24	13
Women	27	38
Selection source	Pathology database	RIS search and review
Inclusion criteria	Age older than 18 yr Pathologically proven MTS	Age older than 18 yr Brain and orbital MRI Coronal FLAIR images extending across hippocampi
Exclusion criteria	Preoperative coronal FLAIR through hippocampi not available	Seizures Known or imaging suspicion of neurologic disease known to affect hippocampus Reported hippocampal abnormalities
Indication for MRI	Refractory epilepsy	Diplopia, cranial neuropathy, visual dysfunction, optic neuropathy, papilledema, retrobulbar pain, ptosis, ocular findings
MR imaging magnet strength (No.)	3T (36) 1.5T (15)	3T (6) 1.5T (45)
Coronal 2D FLAIR parameters		
Thickness (mm)	3	3
FOV (mm)	180 × 180	166 × 190
TR (ms)	9000–11,000	9000–10,000
TE (ms)	80–110	80–110
TI (ms)	2500	2500
Matrix	256 × 256	256 × 224

Note:—RIS indicates radiology information system.

FIG 1. Coronal FLAIR images (A–E) across the medial temporal lobes in patients with pathologically confirmed right-sided (A, C, and E) and left-sided (B and D) MTS. Corresponding images following image processing (A1–E1) demonstrate confluent areas of marked exaggeration of signal intensity of the diseased hippocampi. Note a similar exaggeration of signal intensity to a smaller extent in the right hippocampus (arrow) in B1, presumably indicating bilateral disease.

increased SI in 2%–4.9% (average, 3.6%) of control hippocampi (Fig 2).

Effect on Confidence Ratings

Image processing resulted in an increase in median SI rating for diseased hippocampi ($P < .001$, Table 2) and a decrease in the

median SI rating for both left- ($P = .03$) and right-sided ($P = .003$) hippocampi in controls.

Effect on Readers' Diagnostic Performance

An improvement in the average sensitivity, specificity, positive predictive value, negative predictive value, and accuracy was seen

after processing (Table 3). The average sensitivity increased by >10% (Table 3), and readers were able to detect hippocampal signal abnormality in 4/10 (40%) cases reported as having normal findings on the original clinical reports.

Effect on Interobserver Reliability

Processing resulted in an improvement in the interobserver agreement in SI ratings for cases of MTS from moderate (Fleiss $\kappa = 0.4$; 95% CI, 0.2–0.56) to almost perfect (Fleiss $\kappa = 0.88$; 95% CI, 0.80–0.97).⁹ For control hippocampi, interobserver agreement improved from slight to moderate.⁹

FIG 2. Representative postprocessed coronal FLAIR images across the medial temporal lobes of 5 controls without seizures. Processing did not result in any alteration of hippocampal signal (A and B) for most control hippocampi. While punctate (C and D) foci of signal exaggeration were noted in some control hippocampi, false-positive confluent regions of increased intensity mimicking MTS (E) were observed in the bilateral hippocampi of 1 (2%) control.

Table 2: Effect of image processing on signal intensity ratings for subjects with MTS, right-sided control hippocampi, and left-sided control hippocampi on a 5-point scale^a

	Median	Minimum	25th Percentile	75th Percentile	Maximum	P
Subjects	4.00	1.00	1.00	2.00	4.00	<.001
Subjects (processed)	5.00	1.00	1.00	2.00	5.00	
Controls (R)	1.00	1.00	1.00	1.50	3.50	<.01
Controls (R, processed)	1.00	1.00	1.00	1.00	5.00	
Controls (L)	1.00	1.00	1.00	1.50	2.00	.03
Controls (L, processed)	1.00	1.00	1.00	1.00	5.00	

Note:—R indicates right; L, left.

^a1, Definitely normal; 2, probably normal; 3, possibly normal; 4, probably abnormal; 5, definitely abnormal.

DISCUSSION

In our study, an easily recognizable increase in the contrast-to-noise ratio of diseased hippocampi by the image processing^{6,7} translated into substantial improvement in sensitivity when present and slight improvement in specificity when absent. Our results indicate that this processing may help detect MTS in some patients with focal epilepsy with otherwise normal MR imaging findings,¹⁰ thereby allowing earlier diagnosis and treatment. An improvement in interobserver agreement may make this processing particularly helpful for nonexpert readers, prompting a timely referral to experts.

Unlike volumetry-based techniques,^{11,12} the image processing used in our study relies on highlighting MTS-related signal abnormality. Thus, it is similar to other techniques such as T2 relaxometry and automated FLAIR analysis but may be more generalizable because it does not require comparison with normative data.^{13–16}

CONCLUSIONS

The image-processing algorithm tested by us can improve detection of MTS on MR imaging. In view of a small possibility of false-positive effects of processing, this technique should serve as a complement to a complete epilepsy protocol MR imaging, interpreted in the context of clinical history.
