ABSTRACT

BACKGROUND AND PURPOSE: Both CT angiography and digital subtraction angiography are used to detect aneurysms in patients with subarachnoid hemorrhage. We examined a large multihospital data base to determine how practice is evolving with regard to the use of CT angiography and DSA in patients with ruptured cerebral aneurysm.

MATERIALS AND METHODS: The Premier Perspective data base was used to identify hospitalizations of patients treated with clipping or coiling of ruptured cerebral aneurysms from 2006–2011. Billing information was used to determine pretreatment and posttreatment use of DSA and CT angiography during hospitalization.

RESULTS: A total of 4972 patients (1022 clipping, 3950 coiling) at 116 hospitals were identified. The percentage of patients with SAH who underwent pretreatment CT angiography significantly increased from 20% in 2006 to 44% in 2011 (P < .0001), whereas the percentage of patients who underwent DSA remained unchanged from 96–94% (P = .28). This CT angiography trend was observed in coiling patients (17–42%, P < .0001) and clipping patients (32–54%, P < .0001). There was a significant increase in the percentage of patients who underwent posttreatment imaging from 41% in 2006 to 48% in 2011 (P = .0037). This trend was observed in clipping patients (33–65%, P < .0001) but not in coiling patients (43–45%, P = .62).

CONCLUSIONS: For the pretreatment evaluation of ruptured aneurysms, the use of CT angiography increased from 2006–2011 without a corresponding decrease in the use of DSA. These results raise the question of potential redundancy without added clinical value of the second test.

The standard examination to evaluate for a source of subarachnoid hemorrhage for decades has been conventional angiography, which has now evolved into digital subtraction angiography. This is reflected in the American Heart Association/American Stroke Association guidelines for the management of aneurysmal SAH, which strongly recommend DSA in their class I recommendations.1 In recent years, however, surgery without DSA on the basis of CT angiography has been advocated.2–5 A recent meta-analysis concluded that CT angiography can be used as a primary examination tool in the diagnostic work-up of patients with SAH,6 but that conclusion has been questioned because of weaknesses of CT angiography in the detection of small aneurysms and aneurysms adjacent to the skull base.7–9 Whether

the imaging method used is DSA or CT angiography, the imaging must identify the source of bleeding, most commonly an aneurysm. We evaluated a large, multihospital data base to determine how practice is evolving with regard to the use of CT angiography and DSA in patients with ruptured cerebral aneurysm.

MATERIALS AND METHODS

Study Population and Data Retrieval

The Perspective data base is a voluntary, fee-supported collection of data developed by Premier, Inc, to assess quality and resource use.10 As of 2011, the Perspective data base contained information from more than 600 US hospitals and consisted of approximately 15% of hospitalizations nationwide. This data base contains detailed hospitalization information, including patient and hospital demographics, diagnoses, and all billed items including procedures and diagnostic tests administered in relation to the day of admission. Because the Perspective data base consists of only de-identified patient and hospital data, our institutional review board deemed this study exempt from review and patient consent.

Patients who presented with subarachnoid hemorrhage (ICD-
9-CM diagnostic code 430) from 2006–2011 were identified. Patients were included if they underwent aneurysmal clipping (ICD-9 procedural code 39.51, "clipping of aneurysm") or coiling (ICD-9 procedural codes 39.52, "other repair of aneurysm") in 9046 cases/year. The percentage of patients who underwent clipping (17% [301/1589], P < .0001) or hospitals that performed both clipping and coiling (61%, 150/247) compared with hospitals that predominantly performed coiling (34%, 765/2251, P < .0001) or hospitals that performed both procedures (34%, 841/2474, P < .0001). For clipping patients, 68% (570/1022) underwent CT angiography only, and 24% (242/1022) underwent bothDSA and CT angiography. For coiling patients, 67% (2646/3950) underwent DSA alone and 33% (1304/3950) underwent bothDSA and CT angiography.

The use of pretreatment CT angiography and DSA varied, depending on the hospital. Teaching hospitals had significantly higher rates for the use of CT angiography (40% [1562/3383] versus 25% [391/1589], P < .0001) and lower rates for the use of DSA (93% [3145/3383] versus 96% [1521/1589], P < .0001) compared with nonteaching hospitals. High-volume centers (≥20 cases/year) had higher rates for the use of DSA (96% [2844/2962] versus 91% [1822/2010], P < .0001) and lower rates for the use of CT angiography (33% [990/2962] versus 38% [763/2010], P = .0011) compared with low-volume centers. Rates for the use of DSA were higher in the Northeast (95% [1477/1563]), South (94% [1977/2102]), and West (92% [643/704]) hospitals compared with Midwest hospitals (89% [569/603]). Rates for the use of CT angiography were higher in Northeast hospitals (43% [672/1563]), compared with South (32% [676/2102]), West (33% [220/704]), and Midwest (31% [185/603]) hospitals.

The percentage of patients with SAH who underwent pretreatment CT angiography significantly increased from 20% (157/771) in 2006 to 44% (377/852) in 2011 (P < .0001), whereas the percentage of patients who underwent DSA remained unchanged from 96% (734/771) to 94% (800/852) (P = .28). The fraction of patients who underwent pretreatment CT angiography increased from 2006–2011 in patients undergoing coiling (17% [104/604] to 42% [296/702], P < .0001) and in patients undergoing clipping (32% [53/167] to 54% [81/150], P < .0001). The fraction of patients who underwent DSA decreased from 84% (140/167) to 77% (115/150) (P = .12) for patients treated with clipping. All coiling patients underwent DSA.

**Posttreatment Imaging**

Trends in posttreatment imaging are shown in Fig 2. Overall, 43% (2162/4972) of patients who received treatment for SAH underwent imaging after clipping or coiling, with 22% (1096/4972) receiving DSA only, 12% (575/4972) receiving CT angiography only, and 10% (491/4972) receiving both DSA and CT angiography. Rates for the use of posttreatment imaging were higher in hospitals that predominantly performed clipping (52% [1180/2251]) compared with hospitals that predominantly performed clipping (40% [1562/3873]) or coiling (25% [391/1589], P < .0001) (versus nonteaching) 699 (68%) 2684 (68%)

**RESULTS**

**Study Population**

A total of 4972 patients were identified, of which 1022 were clipping cases and 3950 were coiling cases. Patient demographic characteristics are shown in Table 1. A total of 116 hospitals were represented in the 2006–2011 timeframe. Most hospitals were urban, and more than half were teaching hospitals.
clipping (34% [85/247], \( P < .0001 \)) or hospitals that performed both procedures (36%, [897/2474], \( P < .0001 \)).

Rates for the use of posttreatment CT angiography and DSA varied, depending on the hospital. Teaching hospitals had a similar rate for the use of DSA (31% [1057/3383] versus 33% [530/1589], \( P = .14 \)) but a higher rate for the use of CT angiography (22% [761/3383] versus 19% [305/1589], \( P = .0085 \)) compared with nonteaching hospitals. High-volume centers (\( \geq 20 \) cases/year) also had similar rates for the use of DSA (31% [920/2962] versus 33% [667/2010], \( P = .12 \)) but higher rates for the use of CT angiography (23% [684/2962] versus 19% [382/2010], \( P = .0011 \)) compared with low-volume centers. Rates for the use of DSA were higher in West hospitals (40% [282/704]) compared with South (29% [609/2102]), Northeast (31% [491/1563]), and Midwest (34% [205/603]) hospitals. Rates for the use of CT angiography were higher in Midwest hospitals (30% [180/603]) compared with Northeast (22% [348/1563]), South (19% [391/2102]), and West (21% [147/704]) hospitals.

There was a significant increase in the percentage of patients who underwent posttreatment imaging from 41% (317/771) in 2006 to 48% (412/852) in 2011 (\( P = .0037 \)). This increase was attributable to the increase in the rate for the use of CT angiography from 15% (117/771) to 26% (221/852, \( P < .0001 \)). Patients treated with clipping were increasingly subjected to posttreatment imaging from 2006–2011. The fraction of clipping patients who underwent posttreatment imaging significantly increased from 33% (55/167) in 2006 to 65% (97/150) in 2011 (\( P < .0001 \)), with increases in the rate for the use DSA alone (from 22% [36/167] to 37% [55/150], \( P = .0041 \)), CT angiography alone (from 5% [9/167] to 12% [18/150], \( P = .0436 \)), and both DSA and CT angiography (from 6% [10/167] to 16% [24/150], \( P = .0058 \)). Conversely, the fraction of coiling patients who underwent posttreatment imaging increased minimally from 43% (262/604) to 45% (315/702), \( P = .62 \).

**DISCUSSION**

Our study demonstrates that most patients continue to undergo DSA before clipping or coiling treatment of a ruptured aneurysm,
but 20% of patients treated with clipping were imaged with CT angiography only. Rates for the use of CT angiography were higher in teaching and high-volume medical centers compared with nonteaching and low-volume medical centers. We also found higher rates for the use of CT angiography at centers that predominantly perform clipping compared with centers that predominantly perform coiling. DSA has historically been used to diagnose aneurysms in the setting of SAH, and the use of CT angiography in this context is a recent phenomenon. Rates for the use of DSA did not decrease substantially from 2006–2011, indicating that CT angiography tends to be used in most cases as a study in addition to DSA rather than as a replacement of DSA. Performance of both CT angiography and DSA before treatment of an aneurysm can increase the cost of treatment and the risk of contrast-induced nephropathy relative to the use of either technique alone, with unclear clinical benefit in many cases.

Although every patient who is treated with coiling undergoes DSA of the aneurysm being treated, it may not be a complete, 4-vessel DSA if a CT angiogram is deemed adequate for evaluation of the remaining blood vessels. We are not able to determine the degree of completeness of the DSA in this study; therefore we cannot ascertain how often CT angiography led to an abbreviated DSA.

Because of the noninvasive nature of CT angiography relative to DSA, an argument might be made that the use of CT angiography might be safer than the use of DSA. Through the use of the data base in this study, we cannot accurately assess complications of cerebral angiography to determine whether avoiding DSA by performing CT angiography resulted in better patient outcomes. Because the risk of permanent sequelae from DSA performed in patients with SAH is very low,11 an improvement in safety resulting from avoidance of DSA would be difficult to confirm. Even at centers that generally use DSA as the primary imaging, CT angiography might occasionally be used in the situation of an aneurysm causing parenchymal hematoma requiring urgent surgery, which occurs most commonly with middle cerebral artery aneurysms.

Patients treated with clipping were increasingly subjected to posttreatment CT angiography and/or DSA imaging from 2006–2011, whereas posttreatment imaging of patients undergoing coiling remained fairly constant. The use of more imaging after clipping compared with coiling might be at least partly because all patients undergoing coiling receive angiographic assessment at the end of the procedure, but patients undergoing clipping often do not receive angiographic assessment. We are not able to identify intraoperative DSA in the clipping cohort. This increasing trend may suggest an increasing desire by surgeons to get confirmation of adequate clipping with DSA. CT angiography and DSA in the days after clipping or coiling might be performed to evaluate the treatment result or to evaluate vasospasm. Vasospasm and delayed ischemic deficits occur less frequently in patients treated with coiling relative to those treated with clipping,12 which might contribute to less DSA and CT angiography after the aneurysm is treated by coiling.

This study has several limitations. First, this study is retrospective, and the decision of whether to perform CT angiography or DSA is ultimately made by the provider. Second, indications for imaging are not available in the Perspective data base; therefore, the clinical decision-making process for each hospitalization and the reasons that providers chose CT angiography, DSA, or both modalities are unknown. The implications of our findings may be different for pretreatment and posttreatment imaging because they have different indications. Third, the Perspective data base only captures imaging that was performed during hospitalization. Imaging that may have been performed immediately before or after hospitalization would therefore have been missed. Fourth, the data base is not a random sampling of hospitals, and therefore results may not be representative of all hospitals or hospitalizations. Fifth, some coding inaccuracies undoubtedly occur that can affect the retrospective evaluation of an administrative data base. Such coding inaccuracies are unlikely to lead to misrepresentation of overall trends in the use of imaging. Sixth, whereas our study shows an increasing trend in the use of CT angiography, the level of use of DSA and CT angiography considered optimal or appropriate is unknown. Finally, the findings of our study are only applicable to ruptured aneurysms. The use of DSA and CT angiography may be different with unruptured aneurysms or SAH from other causes.

CONCLUSIONS

For the pretreatment evaluation of ruptured aneurysms, the use of CT angiography increased from 2006–2011, but without a corresponding decrease in the use of DSA. The increased use of CT angiography without a corresponding decrease in DSA use raises the question of potential redundancy in the diagnostic tests without added clinical value of the second test.
