Diffusion-Weighted Imaging–Detected Ischemic Lesions following Endovascular Treatment of Cerebral Aneurysms: A Systematic Review and Meta-Analysis

ABSTRACT

BACKGROUND AND PURPOSE: Endovascular treatment of intracranial aneurysms is associated with the risk of thromboembolic ischemic complications. Many of these events are asymptomatic and identified only on diffusion-weighted imaging. We performed a systematic review and meta-analysis to study the incidence of DWI positive for thromboembolic events following endovascular treatment of intracranial aneurysms.

MATERIALS AND METHODS: A comprehensive literature search identified studies published between 2000 and April 2016 that reported postprocedural DWI findings in patients undergoing endovascular treatment of intracranial aneurysms. The primary outcome was the incidence of DWI positive for thromboembolic events. We examined outcomes by treatment type, sex, and aneurysm characteristics. Meta-analyses were performed by using a random-effects model.

RESULTS: Twenty-two studies with 2148 patients and 2268 aneurysms were included. The overall incidence of DWI positive for thromboembolic events following endovascular treatment was 49% (95% CI, 42%–56%). Treatment with flow diversion trended toward a higher rate of DWI positive for lesions than coiling alone (67%; 95% CI, 46%–85%; versus 45%; 95% CI, 33%–56%; \( P = .07 \)). There was no difference between patients treated with coiling alone and those treated with balloon-assisted (44%; 95% CI, 29%–60%; \( P = .99 \)) or stent-assisted (43%; 95% CI, 24%–63%; \( P = .89 \)) coiling. Sex, aneurysm rupture status, location, and size were not associated with the rate of DWI positive for lesions.

CONCLUSIONS: One in 2 patients may have infarcts on DWI following endovascular treatment of intracranial aneurysms. There is a trend toward a higher incidence of DWI-positive lesions following treatment with flow diversion compared with coiling. Patient demographics and aneurysm characteristics were not associated with DWI-positive thromboembolic events.

Coil embolization and flow diversion have proved highly efficacious options for the endovascular treatment of intracranial aneurysms. However, both techniques are associated with potential periprocedural complications, including aneurysm rupture, transient ischemic attacks, and ischemic stroke. Small, silent infarcts caused by thromboemboli are often seen on postprocedural diffusion-weighted imaging. While many of these lesions remain ostensibly asymptomatic, the long-term effects of such tiny infarcts remain unclear.1–3

Previous studies have reported that the rate of ischemic lesions on postoperative DWI ranges from 10% to 77% following coil embolization4–15 and 51% to 63% following therapy with flow diversion.16–19 However, baseline clinical and angiographic risk factors for postoperative DWI lesions, to our knowledge, have not been fully elucidated previously. We performed a systematic review and meta-analysis for the following: 1) to determine the overall incidence of perioperative infarcts on DWI in patients undergoing endovascular treatment of intracranial aneurysms; and 2) to demonstrate the relationship between treatment type, patient demographics, and aneurysm characteristics with postoperative infarcts on DWI.

MATERIALS AND METHODS

Literature Search and Inclusion Criteria

This systematic review and meta-analysis are reported in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA; http://www.bmj.com/content/339/bmj.b2535) guidelines. An experienced librarian conducted a comprehensive literature search of PubMed, Ovid MEDLINE, and Ovid EMBASE with input from the authors. The search was
performed by using the following keywords: “coiling,” “pipeline,” “flow diverter,” “aneurysm,” “endovascular,” “diffusion,” “restricted diffusion,” “MR imaging,” and “stroke” in both “AND” and “OR” combinations. The search was limited to English articles published from 2000 to April 2016. The inclusion criteria were the following: 1) consecutive series of 10 patients who underwent endovascular treatment of intracranial aneurysms with endosaccular coiling or flow diversion, and 2) DWI examination performed within 5 days of endovascular treatment in all patients. Exclusion criteria were the following: 1) patients who had no lesions on DWI, and 5) studies for which an English translation was not available. Two independent reviewers determined whether the articles met the inclusion and exclusion criteria for this systematic review and meta-analysis. Of the remaining 109 records, 45 were duplicates, abstracts only, or randomized trials to fit the type of included studies. We queried the following study characteristics: 1) patient groups clearly defined, 2) outcomes clearly reported, 3) outcomes clearly reported for each patient group studied, 4) imaging interpreted by an independent reader or interpreted by the operator, 5) readers blinded to the clinical status of the patient, 6) multiple readers used and interobserver agreement assessed, and 7) the study followed a predefined study protocol in which all patients underwent MR imaging at the same time point.

**Risk of Bias Assessment**

We selected items from the Newcastle-Ottawa Scale for nonrandomized trials to fit the type of included studies. We queried the following study characteristics: 1) patient groups clearly defined, 2) outcomes clearly reported, 3) outcomes clearly reported for each patient group studied, 4) imaging interpreted by an independent reader or interpreted by the operator, 5) readers blinded to the clinical status of the patient, 6) multiple readers used and interobserver agreement assessed, and 7) the study followed a predefined study protocol in which all patients underwent MR imaging at the same time point.

**Statistical Analysis**

We estimated from each study the cumulative incidence (event rate at the end of the study) and 95% confidence interval. Because we anticipated marked heterogeneity in the populations and interventions across the various included studies, a random-effects model was used to pool incident rates across studies. Variance was estimated by using the Freeman-Tukey Double Arcsine Transformation. The $I^2$ statistic was used to express the proportion of inconsistency that is not attributable to chance. Analysis was conducted by using the STATA Statistical Software for 2015: Release 14 (StataCorp, College Station, Texas).

**RESULTS**

**Search Results and Patient Population**

The literature search yielded 533 records, of which 424 were deemed irrelevant by reading the title and abstract alone. Of the remaining 109 records, 45 were duplicates, abstracts only, or review articles. Forty-two did not meet our minimum sample size criterion of 10 patients or did not provide data for the number of patients, mean age, sex distribution, mean aneurysm size, aneurysm location, and rupture status.

**Outcomes and Patient Groups**

The primary outcome of this study was the overall rate of DWI performed for thromboembolic events following endovascular aneurysm treatment. We also performed subgroup analyses stratified by treatment type (ie, coiling, stent-assisted coiling, balloon-assisted coiling, and flow diversion), patient sex (male versus female), aneurysm size (small versus large/giant), aneurysm location (anterior versus posterior circulation), and aneurysm rupture status (ruptured versus unruptured). Small aneurysms were defined as those with a maximum diameter of <10 mm.
The rates of postprocedural DWI positive for thromboembolic events are summarized in Table 2. Overall, 49% of all patients had DWI positive for lesions following endovascular treatment of cerebral aneurysms (95% CI, 42%–56%) (Fig 2). The rate of infarcts in patients treated with simple coiling was 45% (95% CI, 33%–56%). This was no different from those treated with balloon-assisted coiling (44%; 95% CI, 29%–60%; \( P = .99 \)) or stent-assisted coiling (43%; 95% CI, 24%–63%; \( P = .89 \)). The rate of DWI positive for lesions in patients treated with flow diversion was 67% and approached statistical significance (95% CI, 46%–85%; \( P = .07 \)) (Fig 3).

Patient sex was not associated with the rate of DWI positive for lesions because 32% (95% CI, 17%–48%) of men and 41% (95% CI, 28%–54%) of women had postoperative infarcts (\( P = .47 \)). In comparing aneurysm size, the rate of DWI positive for thromboembolic events was 52% (95% CI, 39%–65%) for small aneurysms and 61% (95% CI, 34%–86%) for large aneurysms (\( P = .55 \)). The rate of infarcts was not different between patients with aneurysms in the anterior circulation (35%; 95% CI, 25%–47%) and posterior circulation (31%; 95% CI, 9%–59%; \( P = .83 \)). Aneurysm rupture status was not associated with the rate of stroke because 42% (95% CI, 17%–69%) of patients with ruptured aneurysms and 44% (95% CI, 35%–53%; \( P = .87 \)) of those with unruptured aneurysms had DWI positive for lesions.

### Study Heterogeneity and Risk of Bias

I² values were >50% for all outcomes, with the exception of postoperative infarct rate for large aneurysms, indicating substantial heterogeneity. Of the 22 studies included in this meta-analysis, 14 were retrospective and 8 were prospective. Five studies had a high risk of bias, 16 studies had a moderate risk of bias, and 1 study had a low risk of bias as determined by our modified Newcastle-Ottawa Scale criterion.

### DISCUSSION

This systematic review and meta-analysis demonstrated that the overall incidence of DWI positive for thromboembolic events following endovascular treatment of intracranial aneurysms is approximately 50%, with no significant difference between coiling with and without adjunct devices. In addition, there was no association between postoperative DWI positive for lesions and patient sex or aneurysm location, size, or rupture status. There was a trend toward a higher infarct rate among patients treated with flow diversion compared with traditional endovascular coiling techniques; however, this did not reach statistical significance. Because these so-called “clinically silent strokes” have been associated with cognitive decline, depression, and future stroke, these findings highlight the importance of finding new techniques aimed at reducing perioperative infarcts.1–3,24

Several studies have identified risk factors for both symptomatic and asymptomatic lesions positive on DWI following treatment with traditional endovascular techniques. These include large aneurysm size, female sex, age, atherosclerotic disease, and protruding loops of coil.8,13,25,26 Some studies have found that balloon-assisted and stent-assisted coiling increased the risk of thromboembolic complications, while others found no association.5,6,8,10,11,15,27 In contrast, our large study demonstrates that no anatomic or demographic risk factors are associated with this particular postoperative complication. Prior studies have demonstrated that aggressive antiplatelet and anticoagulation therapy is also associated with a reduction in perioperative ischemic
events, but our meta-analysis did not consider this parameter because it was inconsistently reported by the included studies.

One of the interesting findings from our meta-analysis was the trend toward a higher rate of silent infarcts in patients treated with flow diverters compared with those treated with coils alone. While both coils and flow diverters are inherently thrombogenic, treatment with flow diversion is generally associated with a higher rate of thromboembolic complications than with coiling alone. Because flow diverters are high-density metal constructs with large endoluminal surface areas, these devices pose a higher risk of thrombosis in the lumen of the parent artery. Shearing stress from blood flow through the device can cause these thrombi to embolize. In contrast, thrombi that form on lower density coils are less likely to embolize into the bloodstream because of the placement of the coil in the aneurysm sac outside the cerebral circulation.

The high rate of asymptomatic DWI positive for lesions raises questions about the clinical relevance of these tiny strokes. Most thromboembolic events likely do not present as focal neurologic deficits simply because they occur in noneloquent locations. However, many of these so-called "clinically silent" lesions may actually give rise to nongross neurologic deficits. Thus, studies have prospectively explored the relationship between DWI positive for lesions and neuropsychological examination performance and have yielded variable results. Studies from the cardiac literature have found that patients with DWI lesions post-cardiac endovascular and surgical procedures have reduced cognitive function on neuropsychological examinations. However, studies from the coiling and flow-diversion literature have demonstrated no association between the presence of DWI lesions and neuropsychological examination performance. Given these conflicting results, the relevance of DWI positive for lesions to cognitive function remains uncertain, and further study is needed to evaluate the long-term consequences of these infarcts.

Limitations

Our study has several limitations. Many of the studies included in our analysis were retrospective, noncomparative, and nonrandomized. There was substantial variability in methods and the detail in which outcomes were reported. For example, the type of antiplatelet therapy and the time elapsed between the procedures and imaging were inconsistent between studies. Additionally, many articles gave an incomplete account of patient demographics, symptomatic status, and neurologic outcomes. Our study also has publication bias, and we acknowledge the methodologic differences between institutions and the tendency for retrospective studies to only publish positive results. We did not compare outcomes based on the type of anticoagulation and antiplatelet therapy, a parameter that likely influences clot formation and isch-
emic stroke incidence. Similarly, we did not consider the lesion load of each patient and the relationship of this value to predicting symptoms. MR imaging techniques likely differ from institution to institution. It is possible that differences in MR imaging field strength, B0 values, and section thickness affect the overall rate of DWI lesion detection. It is important to consider these limitations when interpreting the results of this meta-analysis.

CONCLUSIONS
Our meta-analysis, which included >2000 patients undergoing endovascular treatment of intracranial aneurysms, demonstrated that the overall rate of postoperative DWI positive for thromboembolic events is approximately 50%, with no differences when comparing coiling techniques, aneurysm characteristics, or patient sex. There was a trend toward a higher rate of thromboembolic complications among those treated with flow diverters compared with those treated with coiling alone. Because the long-term effects of these so-called silent infarcts are unclear, further work is needed to develop techniques to reduce the rate of thromboembolic complications associated with endovascular aneurysm treatment. Given the limitations of this meta-analysis, prospective studies with uniform methods are needed to confirm these results.
