CLINICAL REPORT

ASCENDING AND DESCENDING THORACIC VERTEBRAL ARTERIES

P. Gailloud, L. Gregg, M.S. Pearl, and D. San Millan

ABSTRACT

SUMMARY: Thoracic vertebral arteries are anastomotic chains similar to cervical vertebral arteries but found at the thoracic level. Descending thoracic vertebral arteries originate from the pretransverse segment of the cervical vertebral artery and curve caudally to pass into the last transverse foramen or the first costotransverse space. Ascending thoracic vertebral arteries originate from the aorta, pass through at least 1 costotransverse space, and continue cranially as the cervical vertebral artery. This report describes the angiographic anatomy and clinical significance of 9 cases of descending and 2 cases of ascending thoracic vertebral arteries. Being located within the upper costotransverse spaces, ascending and descending thoracic vertebral arteries can have important implications during spine interventional or surgical procedures. Because they frequently provide radiculomedullary or bronchial branches, they can also be involved in spinal cord ischemia, supply vascular malformations, or be an elusive source of hemoptysis.

ABBREVIATIONS: ISA = intersegmental artery; SIA = supreme intercostal artery; VA = vertebral artery

The cervical portion of the vertebral artery (VA) is formed by a series of anastomoses established between the first 6 cervical intersegmental arteries (ISAs) and one of the carotid-vertebral anastomoses, the proatlantal artery.1-3 The VA is labeled a “postcostal” anastomotic chain (ie, located behind the costal process of cervical vertebrae or dorsal to the rib itself at the thoracic level) to emphasize its location within the transverse foramina. A thoracic VA is a similar postcostal vessel found at the thoracic level.4 A thoracic VA was originally defined as a proximal VA branch curving medially and caudally to enter the ipsilateral C7 transverse foramen or first costotransverse space (Fig 1, right).5 Atypical forms, common in birds and mammals but rare in humans,5-6 include thoracic VAs originating from the supreme intercostal or deep cervical arteries.

Another anastomotic chain found within the upper costotransverse spaces differs from a descending thoracic VA by its caudal origin from a thoracic ISA and its ascending course.7 This exceptional variant corresponds to an ascending thoracic VA (Fig 1, left) and should not be confused with variants such as a vertebral arteria lusoria8-13 or persistent left seventh cervical ISA of aortic origin.14

This report discusses 9 angiographic observations of descending thoracic VAs and 2 cases of ascending thoracic VAs.

CASE SERIES

Descending Thoracic Vertebral Arteries

Nine typical descending thoracic VAs were documented by DSA in 9 patients between 2006 and 2015 (Table). The variation was unilateral in 8 instances. In 1 patient, a contralateral thoracic VA was documented by CTA only. The bifurcation into the cervical and thoracic VAs was found at C7–T1 (5 instances, 56%) or C6–C7 (4 instances, 44%). The descending thoracic VA was right-sided in 8 cases (89%).

The ISAs provided by the descending thoracic VAs were either complete (ie, including medial, dorsal, and lateral branches) or incomplete, with only the medial branch present; the other branches then came from the supreme intercostal artery (SIA). Most commonly, the descending thoracic VA provided the second (T2) and third (T3) thoracic ISAs completely, as well as 1 or more partial ISA proximally (T1 in 5 cases, C7 and T1 in 1 case). Isolated medial branches were also noted at C7 or T2 (once each).

In 2 observations, the descending thoracic VAs were extending out of the FOV after branching off the third thoracic ISA (T3). Descending thoracic VAs branched off important anterior radiculomedullary arteries in 5 instances (56%), 4 times at T2 and once at T1.

Received August 5, 2016; accepted after revision September 23.

Case 1. Right descending thoracic VA documented (Fig 2) in a 64-year-old man.

Case 2. Right descending thoracic VA documented in a 67-year-old woman (Fig 3).

Case 3. Bilateral descending thoracic VAs documented in a 59-year-old woman (Fig 4).

Case 4. Right descending thoracic VA documented in 30-year-old man (Fig 5A, -B). An ipsilateral costocervical angiogram illustrates the characteristics distinguishing a descending thoracic VA from an SIA (Fig 5C, -D).

Case 5. A 47-year-old woman with a right descending thoracic VA branching off the third thoracic ISA as well as a conspicuous bronchial artery (Fig 6).

Ascending Thoracic Vertebral Arteries

Case 1. A 20-year-old man with bullet fragments in the posterior fossa. The right VA injection showed minimal reflux into the left V4 segment, with prompt wash-off indicating the presence of a patent left VA, which was identified as the cranial continuation of the left T2 ISA (Fig 7A, -B). Enlargement of the left T1 and T2 costotransverse spaces was noted (Fig 7C).

Case 2. A 64-year-old man investigated for gait disturbance. A left VA originating from the thoracic aorta and passing through the left T2 and T1 costotransverse spaces (Fig 8A) is identified as a left T2 ISA (Fig 8B).

DISCUSSION

Developmental Anatomy of the VA

Hislop divided the VA into cranial and cervical portions on the basis of their developmental history. Appearing first, the cranial portion principally consists of the proatlantal artery, which is associated with the first cervical nerve. The anterior radiculomedullary branch stemming from the proatlantal artery becomes the distal VA; it divides into ascending and descending rami, which respectively turn into the proximal basilar artery and the vertebral root of the anterior spinal artery.\textsuperscript{16-18} The cervical portion of the VA subsequently forms as a succession of anastomoses between the first 6 ISAs, which connect cranially with the proatlantal artery and caudally with the subclavian artery (sixth ISA).\textsuperscript{2} The final configuration of the VA depends on which primitive ISA becomes its adult origin. Most often, the proximal VA, being derived from the sixth cervical ISA, originates from the subclavian artery and enters the C6 transverse foramen. Variations are identified by the level at which they enter the transverse canal rather than by their origin. For example, a VA derived from the seventh cervical ISA always enters the C7 transverse foramen but can arise from the aorta or from the subclavian artery via the SIA.\textsuperscript{19}

A thoracic VA is an anastomotic chain passing through 1 or more costotransverse spaces.\textsuperscript{4,19}

*Question mark indicates that the caudal extension of the descending thoracic VA was beyond the FOV.

*Question mark indicates that motion artifacts prevented evaluating the presence of a proximal medial branch.
Walsham described thoracic VAs in the following manner: “The artery would here appear to be homologous to the vertebral artery in the neck, as both lie between homologous parts, the anterior part of the transverse process of the cervical vertebra being the homolog of the neck and head of the dorsal rib, and the posterior part of the cervical transverse process that of the transverse process of the dorsal vertebra.”

While any postcostal anastomosis established between 2 or more thoracic ISAs answers this definition (eg, a T3–T4 intercostal trunk linked by a postcostal anastomosis), the term “thoracic VA” is generally reserved for variants connected with or continuing as a cervical VA. These variations can be divided into 2 groups with similar developmental mechanisms but different connection patterns: the ascending and descending thoracic VAs. Descending thoracic VAs generally share a common origin with the cervical VA but may also be connected to the SIA or deep cervical artery (atypical forms of Krassnig) (Figs 9 and 10, right). An alternate configuration reported by Bühler consists of a first thoracic ISA originating from the aorta and continuing as a descending thoracic VA to branch off additional ISAs (Fig 10, left).

Ascending thoracic VAs arise from the thoracic aorta and continue cranially as a cervical VA. A thoracic VA can occasionally show mixed characteristics by connecting both at the cervical and thoracic levels (eg, Walsham’s case). Dubreuil-Chambardel reviewed the cases of ascending and descending thoracic vertebral arteries published before 1926.

Two configurations developmentally similar to thoracic VAs must be distinguished from this group of variations because they fail to pass through at least 1 costotransverse space. These include more...

**FIG 2.** A 64-year-old man with a right descending thoracic vertebral artery. A, DSA, right VA injection, posteroanterior projection, shows a VA originating from the subclavian artery and dividing into ascending cervical (large white arrow) and descending thoracic (white arrowhead) VAs at the C7–T1 level. The descending thoracic VA provides the medial branches of C7 (small white arrow) and T1 (double small white arrow) and complete sets of branches for the T2 and T3 ISAs. The second thoracic ISA provides a prominent anterior radiculomedullary artery (small black arrow), which supplies the anterior spinal artery (black arrowheads). B, CTA, coronal reconstruction at the level of the transverse foramina. The ascending (large white arrow) and descending (white arrowhead) branches of the VA are identified. The small gray arrows point to the descending thoracic VA down to its termination at T3 (small black arrow). C, CTA, multilevel axial reconstructions, shows the course of the descending thoracic VA (small gray arrows) from its origin at C7–T1 (white arrowhead).

**FIG 3.** A 67-year-old woman with a right descending thoracic vertebral artery. A, DSA, right VA injection, posteroanterior projection. The VA divides into ascending cervical (large white arrow) and descending thoracic (white arrowhead) VAs at the C7–T1 level. The descending thoracic VA provides the medial branch of T1, which gives off a prominent anterior radiculomedullary artery (small black arrow). Note that the descending thoracic VA extends beyond the FOV and may provide additional ISAs. A prominent T2 dorsal (muscular) branch is seen coursing medially and caudally (black arrowhead) and should not be confused with a bronchial artery. B, DSA, right VA injection, nonsubtracted posteroanterior projection, documents the close relationship between the descending thoracic VA and the cervical pedicles (asterisks), notably at the level of the transverse foramina (small white arrows).
cranially bifurcating trunks with a descending branch that remains within the cervical region (Fig 11A) and VAs of aortic origin entering the seventh transverse foramen (Fig 11B). The latter corresponds to persistent seventh cervical ISAs; their aortic origin remains close to the left subclavian artery.14 A vertebral arteria lusoria8 (ie, a right VA originating distal to the left subclavian artery) also known as a “distal aortic origin of the VA” or “fourth branch of the aortic arch,”9-13 must be distinguished from a thoracic VA as well (though a vertebral arteria lusoria of low origin with a thoracic component is conceivable but, to our knowledge, not reported).

**Descending Thoracic Vertebral Arteries**

The first case of a descending thoracic VA known to the authors was reported by Quain in 1844 (Fig 12).22 Pensa23 confirmed the observation of Quain in 1905 and documented the concomitant existence of thoracic VAs and SIAs (Fig 13). Approximately 70 years later, Newton and Mani24 offered the first angiographic documentation of a descending thoracic VA (labeled as a “vertebral origin of the SIA”), while Chiras et al25 published a correctly identified bilateral observation in 1982.

It is important to distinguish descending thoracic VAs from SIAs (both are usually present simultaneously19). A major difference is topographic in nature: A thoracic VA is a postcostal vessel passing through costotransverse spaces, while an SIA is a precostal vessel lying in a more lateral position (Figs 1 and 5). Other variations that should not be confused with a descending thoracic VA include VAs originating from the SIA via the seventh cervical ISA (which is often mislabeled as an SIA or costocervical trunk origi-
nating from the VA) (Fig 14) and aberrant bronchial arteries arising from the proximal VA (Fig 15). On the other hand, a VA originating from the SIA via a thoracic ISA (eg, T1 or T2) and entering the first or second costotransverse space would represent an atypical form of an ascending thoracic VA.

Note that in Pensa’s illustration,23 the descending thoracic VA does not give off the lateral branch of T1 (Fig 8). This observation is consistent with our findings: In all except 1 case, the descending thoracic VA branched off at least 1 incomplete proximal ISA, most commonly T1. Adachi et al19 reported 4 observations of right-sided descending thoracic VAs entering the seventh transverse foramen, all coursing down through the first 3 costotransverse spaces, as in the current report.

The prevalence of descending thoracic VAs may be approximated by considering that 9 cases were documented at our institution (Division of Interventional Neuroradiology, The Johns Hopkins Hospital) during a 5-year period, with an average caseload of approximately 300 diagnostic angiograms per year, hence a prevalence of about 0.6%.

**Ascending Thoracic Vertebral Artery**

While Adachi et al19 recorded the existence of ascending thoracic VAs in his anatomic material (Fig 16), no angiographic observation has, to our knowledge, been published so far. In one of our patients with suspected VA dissection, the left VA was found to originate from the second left thoracic ISA (T2). Enlarged left costotransverse spaces at T1 and T2 consistent with the passage of a left ascending thoracic VA were visible on a chest CT. Our second observation was incidental.

**Comparative Anatomy**

The existence of animal species with vascular configurations matching human anatomic variants helps authenticate these variations and understand their development.26 Pensa23 published 2 avian examples of adult anatomy respectively equivalent to typical ascending and descending thoracic VAs in the chicken and the pigeon (Fig 17), while descending thoracic VAs of costocervical origin (atypical form of Krassnig5) seem constant in dogs.6 Comparative data may also predict variations not yet documented in humans. For example, all 7 pairs of intercostal arteries
in the European pond turtle are branches of an anastomotic chain similar in nature to a VA, an observation suggesting that such extensive longitudinal vertebral chains may, as extreme variants, exist in humans as well.

FIG 8. A 64-year-old man with a left ascending thoracic VA. A, CTA, coronal MIP reconstruction, shows the origin of the left T2 ISA (white arrow) and its passage through the T2 and T1 costotransverse spaces. The vessel then continues cranially as the cervical VA. B, CTA, oblique MIP reconstruction, documents the T2 posterior intercostal artery (arrowhead), therefore identifying the ascending thoracic VA as being derived from the second thoracic ISA (arrow).

FIG 9. A 31-year-old woman with an atypical descending thoracic VA. A, DSA, left supreme intercostal artery injection, posteroanterior projection, subtracted view shows an example of a descending thoracic VA originating from the supreme intercostal artery (atypical form of Krasnig5); in this case, there is no connection with the cervical VA. The supreme intercostal artery provides the C7 (a) and T1 (b) ISAs as well as the lateral branch of the T2 ISA (c). A prominent ascending branch curves sharply downward to enter the first costotransverse space and continues caudally as a descending thoracic VA (black arrow) passing through the T2 and T3 the costotransverse spaces. This descending thoracic VA provides the T3 ISA (d) and the medial branch of the T2 ISA (gray arrowhead). Note the opacification of the T4 ISA (e) via a small paravertebral anastomotic connection (as shown in Fig 1, right side). The C7 ISA provides both an anterior (black arrowhead) and a posterior (white arrowhead) radiculo-medullary artery. B, DSA, left supreme intercostal artery injection, posteroanterior projection, nonsubtracted view of same image.

FIG 10. Schematic representation of 2 types of descending thoracic VA variants. The descending thoracic VA (atypical form of Krasnig5) depicted on the right side is, as in Fig 9, connected with the supreme intercostal artery rather than the cervical VA. In the configuration shown on the left side (atypical form of Bühler21), the descending thoracic VA is the downward continuation of a thoracic ISA of aortic origin. a. indicates artery.

FIG 11. Examples of vertebral configurations similar to but distinct from thoracic VAs. A, CTA, sagittal MIP reconstruction. This case shows a descending branch with an appearance similar to that of a descending thoracic VA (arrow). However, the bifurcation is located at C5–C6, and the descending branch stops at C7, short of the first costotransverse space. There is, therefore, no thoracic segment. B, CTA, coronal MIP reconstruction, shows a vertebral artery originating from the aorta distal to the subclavian artery and entering the seventh transverse foramen (arrow). This vessel corresponds to a persistent seventh ISA and has no thoracic component.
Clinical Relevance

Spine surgeons and interventionists must be aware of the existence of thoracic VAs because their injury during a vertebral procedure may prove significant, notably in cases of ascending thoracic VAs supplying the posterior fossa. One or more abnormally conspicuous costotransverse space may be the only sign indicating the presence of such a variant on preoperative imaging (Fig 7C).

These variants also have a significant angiographic importance. Thoracic VAs may, through one of their frequent radiculomedullary branches, supply a spinal vascular malformation or be involved in the development of spinal cord ischemia. Similarly, because ascending thoracic VAs participate in the vascularization of the posterior fossa, they may play a role in vertebrobasilar in-
sufficiency or supply an intracranial aneurysm or vascular malformation. They can also represent a source of embolic material, either of atheromatous or iatrogenic origin.

Finally, the possibility that a descending thoracic VA can contribute to the bronchial vascularization must be kept in mind when investigating a hemoptysis of elusive origin.

In summary, thoracic VAs are anastomotic chains similar to normal cervical VAs but extending through at least 1 costotransverse space. They can be divided into ascending and descending types that differ by their origin, course, and clinical implications.
