ABSTRACT

SUMMARY: Consumption of over-the-counter dietary supplements to reduce body weight is common among the population. Thermogenics are herbal combinations that claim to produce a fat-burning process through an increase in the cellular metabolic rate and greater cellular energy consumption, having a high risk for patients developing toxic leukoencephalopathy. We present a series of 6 patients with acute neurologic symptoms and MR imaging showing restricted diffusion and decreased apparent diffusion coefficient values (mean value, 400 mm²/s × 10⁻¹¹) in the entire corpus callosum compatible with a cytotoxic lesion of the corpus callosum. Although patients responded favorably to the product discontinuation with rapid recovery of neurologic symptoms, there was a more prolonged resolution on imaging alterations. Because of the widespread availability and unregulated nature of thermogenic dietary supplements, physicians must be aware of the clinical and radiologic characteristics of these potential complications of their use.

ABBREVIATION: CLOCC — cytotoxic lesion of the corpus callosum

Consumption of over-the-counter dietary supplements to reduce body weight is common among the population. Thermogenics are herbal combinations that aim to augment fat-burning by producing an increase in the cellular metabolic rate and greater cellular energy consumption. These supplements are available in most countries and can be purchased over the Internet without a prescription. Although local drug-regulation agencies have warned against the indiscriminate use of these products, they are still widely available under various brand names.

Recently, there have been reports of severe-yet-reversible toxic leukoencephalopathy related to the intake of thermogenic supplements. Characteristic MR imaging findings reveal intramyelinic edema that has a predilection for the corpus callosum. These MR imaging changes have been recently termed “cytotoxic lesions of the corpus callosum” (CLOCCs). Previously, similar findings were described as mild encephalitis or encephalopathy with reversible splenial lesions and reversible splenial lesion syndrome among others. However, not all cases are mild, reversible, or limited to the splenium.

It is believed that these lesions are a result of an inflammatory cascade of changes manifested as cytotoxic edema secondary to an increased influx of water molecules in astrocytes and neurons caused by the release of the inflammatory cytokines interleukin-1 and interleukin-6. These interactions create feedback loops that increase extracellular glutamate levels. The increased quantity of extracellular glutamate has an excitatory effect at membrane receptors such as the α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) and N-methyl-D-aspartate (NMDA) receptors, as well as aquaporins and Na⁺/K⁺ pumps. The most affected region of the corpus callosum is the splenium due to its higher density of glutamate and cytokine receptors. The purpose of this research was to contribute to the understanding of toxic causes of CLOCCs, to describe the clinical and MR imaging findings of CLOCCs caused by thermogenic dietary supplements, and thus to expand the body of literature on the diagnosis of this condition.

Case Series

This case series report was performed under institutional review board approval. An observational, descriptive, retrospective study was conducted of both inpatient and outpatient subjects during a 3-year period. We searched the registry of the hospital for cases with clinical and brain MR imaging findings compatible with toxic leukoencephalopathy that reported previous use of thermogenic dietary supplements. As inclusion criteria, we considered...
FIG 1. CLOCCs caused by thermogenic dietary supplements. Axial DWI (A) and corresponding ADC map (B) of case 1 show restricted diffusion representing cytotoxic edema at the corpus callosum. C, Sagittal DWI shows a hyperintense corpus callosum, cerebral commissures, and fornix in case 2. D and E, Axial DWI and corresponding ADC map from case 4 show more extensive cytotoxic edema that affects the entire corpus callosum and cerebral white matter. F, Sagittal DWI of case 5 reveals an enlarged and edematous corpus callosum, fornix, and cerebral commissures with involvement of the peripheral cerebral white matter, cerebral peduncles, and brain stem, along with the optic nerves.

those 18 years of age and older who had a history of thermogenic supplement intake during the previous 6 months, acute neurologic symptoms at presentation, and white matter brain alterations on MR imaging, characterized as diffusion-weighted imaging ($b=1000$) restriction with decreased apparent diffusion coefficient values. Six patients fulfilled the criteria and were included in this series; all of them were women. The mean age was 33 years (range, 23–43 years); all of the patients had normal body mass index values (mean, 21.01; range, 19.2–23.7) at the time of intake during the previous 6 months; all of them took the recommended dosage of the product. Of the patients, one had a history of social alcohol consumption, 2 were active smokers, one was receiving an antiepileptic drug (phenytoin) and an anticoagulant (acenocumarol) for a previous ischemic stroke, and another was on antidepressant medication (amitriptyline). Regarding the dietary supplement intake, the median time of consumption for the 6 patients was 5.3 months (range, 1–18 months); all of them took the recommended dosage of the product.

At the time of the medical evaluation, headache was present in 5 patients; generalized weakness, in 4; distal paresthesia, in 3; blurred vision, in 3; photophobia, in 2; and phonophobia in 1. The clinical spectrum was nonspecific, ranging from normal examination findings to gait disturbances.

On MR imaging, restricted diffusion with low ADC values (mean, 400 mm$^2$/s × 10$^{-6}$; range, 194–550 mm$^2$/s × 10$^{-6}$) was present in the corpus callosum and cerebral commissures of all 6 patients (Fig 1), while the hemispheric cerebral white matter, brain stem, and dentate nucleus of the cerebellum were affected in 3 (Fig 2). The optic nerve was affected in 3 patients. The signal alteration was less evident on the FLAIR sequence as a subtle hyperintensity in only 3 patients.

After suspending the dietary supplement intake, all neurologic symptoms resolved within a mean time of 2.8 days (range, 1–5 days). A total of 4 patients underwent control MR imaging studies. While 1 patient had complete resolution in the imaging findings at 6 weeks, 1 patient did not show improvement on imaging at 2 months. Only partial resolution of the MR imaging alterations showed in a 10-month control study for 1 patient, and 1 had complete resolution 22 months after the initial MR imaging.

Demographic and MR imaging findings are listed in the Table.

**Patient Presentation**

**Case 1.** A 41-year-old woman with no relevant medical history presented with a progressive generalized headache, blurred vision, disorientation, gait disturbance, and difficulty concentrating. The physical examination revealed only diminished attention and anxiety with normal language fluency. The MR imaging showed diffuse DWI hyperintensity of the entire corpus callosum with extension to the fornices with low ADC values (461–550 mm$^2$/s × 10$^{-6}$) in the structures mentioned above (Fig 1A, -B). The patient had been consuming a thermogenic dietary supplement for 1 month. The supplement was suspended, and the patient was administered glucocorticoid therapy. Neurologic symptoms improved 5 days later. Meanwhile, the MR imaging alterations completely resolved on a control MR imaging after 6 weeks.

**Case 2.** A 30-year-old woman with no relevant medical history was admitted with 2-day distal ascending paresthesia associated with a generalized headache. The physical examination findings were normal. MR imaging showed a hyperintense DWI signal from the rostrum to the splenium of the corpus callosum with bilateral involvement of the cerebral commissures and the fornix columns (Fig 1C), with decreased ADC values (351–475 mm$^2$/s × 10$^{-6}$). The patient revealed a 1-month history of thermogenic intake. The supplement was suspended, and glucocorticoid was administered. All neurologic symptoms improved 3 days later. The patient was then discharged; she missed follow-up appointments.

**Case 3.** A 37-year-old woman with no relevant medical history presented with 7-month distal ascending paresthesia. The physical examination did not reveal any motor involvement, only mild hyporeflexia. A lumbar puncture was performed, which revealed high protein levels (125 mg/dL) with no leukocyte count. Intravenous immunoglobulin was administered on the basis of suspected Guillain-Barré syndrome; however, the patient’s symptoms persisted after 2 months of treatment. The MR imaging...
showed a hyperintense DWI signal of the corpus callosum, cerebral commissures, and fornices, with extension to the periventricular cerebral white matter, associated with discrete, low ADC values (485–524 mm²/s × 10⁻⁶). The patient then revealed a 7-month history of thermogenic supplement intake. Neurologic symptoms improved 3 days after supplement discontinuation. A control MR imaging performed after 2 months showed significant reduction of the DWI brain abnormalities, with only a mild bilateral symmetric edema on the hippocampi.

**Case 4.** A 23-year-old woman with no relevant medical history presented with a 7-day progressive generalized headache associated with blurred vision and left-arm weakness. The physical examination revealed left-arm paresis only. MR imaging showed extensive cytotoxic edema of the corpus callosum, cerebral commissures, peripheral cerebral white matter, brain stem, and dentate nucleus of the cerebellum, with enlargement and hyperintensity of the optic nerves on DWI, with low ADC values (284–370 mm²/s × 10⁻⁶). Loss of gyral cerebral morphology was also present with diminished convexity of the subarachnoid space. The patient had a 3-month history of thermogenic supplement intake. Intravenous glucocorticoid was administered, and notably, the neurologic symptoms improved the day after. The patient was discharged and had no follow-up imaging.

**Radiologic and demographic data for each patient**

**Note:** BMI indicates body mass index; CC, corpus callosum; FR, fornices; CO, cerebral commissures; BS, cerebral brain stem; DN, dentate nucleus of the cerebellum; ON, optic nerves; CH, chiasm; OT, optic tracts.

**FIG 2.** CLOCCs caused by thermogenic dietary supplements. Set of images from case 4 that show cytotoxic edema extending to the peripheral cerebral white matter (row A), brain stem (row B), and dentate nucleus of the cerebellum (row C). Left column, DWI trace images. Middle column, ADC map. Right column, T2WI.

**Case 5.** A 43-year-old woman with a medical history of ischemic stroke 8 years before the onset of new symptoms presented with a 4-month history of blurred vision, intermittent frontal headache, and frequent falling. The physical examination revealed gait ataxia, bilateral dysmetria, and diminished pupillary light reflex. MR imaging showed increased volume and a hyperintense DWI signal of the corpus callosum with decreased ADC values (405–440 mm²/s × 10⁻⁶). Additionally, the hemispheric white matter showed increased signal in T2 and FLAIR sequences, with extension to the brain stem and dentate nucleus and compromised optic nerves, chiasm, and optic tracts. The patient received glucocorticoid therapy and then revealed continuous thermogenic supplement intake for 18 months. The neurologic symptoms improved 5 days after supplement discontinuation. Despite that, the MR imaging alterations were only partially resolved up to 10 months later in serial control studies (Fig 3A–B).

**Case 6.** A 25-year-old woman with no relevant medical history presented with a 2-month progressive, generalized, oppressive headache associated with photophobia and phonophobia that did not improve with oral painkillers. The physical examination revealed left-arm paresis only. MR imaging showed extensive cytotoxic edema of the corpus callosum and cerebral commissures, peripheral cerebral white matter (Fig 2A), brain stem (Fig 2B), and dentate nucleus of the cerebellum (Fig 2C), with hyperintense DWI signal of the corpus callosum with decreased ADC values (194–275 mm²/s × 10⁻⁶). Loss of gyral cerebral morphology was also present with diminished convexity of the subarachnoid space. The patient had a 2-month history of thermogenic supplement intake. Intravenous glucocorticoid was administered, and notably, the neurologic symptoms improved 2 days after supplement discontinuation, whereas the MR imaging findings completely resolved after 22 months (Fig 3C–D).
DISCUSSION

Toxic leukoencephalopathy can be caused by different exogenous agents, and although the clinical and imaging presentation may be severe, it can be reversible. Some of these substances have a predilection for the corpus callosum.\(^5\) Thermogenics are readily available on the World Wide Web as over-the-counter dietary supplements. Herbal preparations consumed by this series of patients shared a combination of botanical and biochemical ingredients like bitter melon (\textit{Momordica charantia}), green tea, horsetail herb (\textit{Equisetum}), bearberry (\textit{Arctostaphylos uva-ursi}), olive, juniper, ginger, yerba mate, grape, cempasuchil flower (\textit{Tagetes erecta}) pigment, L-carnitine tartrate, and microcrystalline cellulose among unspecified others. Some substances found in these compounds, especially the combination of high doses of caffeine and ephedrine analogs, have an action mechanism that increases the rate of fat oxidation and lipolysis with reduced glycogen metabolism.\(^6,7\) Some of these plant molecules have other in vitro metabolic activities. For example, bitter melon is reported to be a bioactive insulin-like structure, which has exhibited a moderate effect on the reduction of blood glucose levels in clinical studies. Most interesting, CLOCCs in adult patients with acute hypoglycemia have a common predilection for the posterior corpus callosum and tracts of deep white matter.\(^8,9\) Thus, in this series, the corpus callosum was more extensively affected in all patients. Bitter melon has also been associated with significant adverse effects, which include anxiety, insomnia, and cardiovascular disorders, caused by stimulation of the central nervous system.\(^9\)

The term “leukoencephalopathy” encompasses a spectrum of diseases that predominantly involve the white matter structure as a result of exposure to a variety of exogenous agents; known causes are chemo- and immunotherapy, antibiotics, and environmental and infectious agents.\(^10\) In some cases, the cause is unknown.\(^11,12\) Although the central nervous system is naturally protected by the blood-brain barrier, some of these agents are known to interfere with or damage this barrier, allowing access of potentially threatening substances to neural tissue. Other agents are fat-soluble; this feature facilitates their distribution into the central nervous system.\(^13\) Acute toxic leukoencephalopathy may have a severe extension and may be reversible both clinically and radiologically.\(^14\) Clinical presentation is nonspecific, depending on the distribution of edema, often including neurologic decline, distal paresthesia, personality changes, memory alterations, headache, and other focal neurologic signs.\(^15\)

Damage usually involves white matter tracts from the periventricular-to-subcortical areas, though other metabolically active areas may be susceptible to neurotoxicity, including the deep gray matter and the brain stem. Therefore, these structures may show changes in acute toxic leukoencephalopathy imaging. Regarding its pathophysiology, theories posit that cytotoxic edema is caused by the increased water molecule influx in neurons and astrocytes. The splenium is the most affected area of the corpus callosum because of its high density of glutamate, and cytokine and drug receptors.\(^4,5,14,16,17\)

Drug agencies around the world have issued health warnings against some of the thermogenic dietary supplements consumed by our series of patients, including the Comisión Federal para la Protección contra Riesgos Sanitarios (COFEPRIS) in Mexico and Agencia Española de Medicamentos y Productos Sanitarios (AEMPS) in Spain and this motivated a recall by the FDA in the United States.\(^18,19\) Nonetheless, these products can still be easily purchased on-line without a prescription under various brand names.\(^3,18,19\)

All the patients in our series had normal body weight with normal body mass index values at the time of examination. They did not indicate that previous obesity or being significantly overweight had motivated them to consume the dietary supplements,
which could be a risk factor for developing CLOCCs. However, due to the limited number of cases, we cannot make assumptions on this issue.

Two of our patients were on antiepileptic or antidepressant medication, both of which have been reported to cause drug-related CLOCCs. The fact that the other 4 patients lack this risk factor makes this association of a comorbid condition less plausible. Even so, there is a need for further analysis on a larger number of patients to determine whether there is any relationship. One patient had a history of social alcohol consumption but no chronic alcoholism that makes this association of a comorbid condition less plausible. Even so, there is a need for further analysis on a larger number of patients to determine whether there is any relationship.

As observed in our series, the clinical symptoms of CLOCCs caused by thermogenic dietary supplements are frequently subtle and may not always prompt subjects to seek medical attention, making it possible that a significant number of cases occur undetected.

Although the clinical neurologic signs and symptoms improved rapidly after the withdrawal of the supplement, the white matter lesions on MR imaging reduced gradually and progressively resolved in a highly variable fashion (6 weeks to 22 months), seemingly dependent on the extension of leukoencephalopathy. There may be signs of peripheral nerve involvement as in case 3, but there is not enough evidence to confirm this possibility. Additionally, we do not know if there is any potential long-term neurologic damage resulting from thermogenic consumption as in other toxic leukoencephalopathies.

Given the lack of regulation in the manufacturing process of these herbal dietary supplements, it is difficult to know if the brain toxicity was caused by a single defective batch, though its widespread presentation for a long period suggests otherwise. Also, the information provided on the label of these products is often incomplete. For example, the labels do not state the specific parts of the plants used. Because the concentration of each active compound could be highly variable, this feature can result in possible toxic combinations not yet identified. It is conceivable that incorrect handling of these ingredients or contamination due to inadequate supervision during fabrication could lead to potentially harmful products.

CONCLUSIONS

Thermogensics are widely available but potentially harmful dietary supplements that have prompted warnings and recalls by international drug regulation agencies; nonetheless, they can still be easily purchased on-line. These herbal preparations being labeled as natural does not mean that they are entirely safe. When used without medical supervision, they can produce toxic neurologic side effects such as CLOCCs. It is not known whether a normal body mass index before consumption could play a role in developing toxicity or if there could be any interactions between the dietary supplements and other substances, such as prescription drugs or over-the-counter medications. With this publication, we add 6 new cases to the 2 previously reported cases of toxic leukoencephalopathy caused by thermogenic dietary supplements and to the toxic etiologies of CLOCCs, making the medical community aware of the clinical and radiologic characteristics of this potential complication.
