Leukoaraiosis May Confound the Interpretation of CT Perfusion in Patients Treated with Mechanical Thrombectomy for Acute Ischemic Stroke

ABSTRACT

BACKGROUND AND PURPOSE: Leukoaraiosis frequently coexists in patients with acute stroke. We studied whether leukoaraiosis could confound the interpretation of CTP findings in patients treated with mechanical thrombectomy.

MATERIALS AND METHODS: We analyzed 236 patients with stroke treated with mechanical thrombectomy and studied with CTP, of whom 127 (53.8%) achieved complete reperfusion. Periventricular white matter hyperintensities on MR imaging and hypodensities on NCCT were assessed through the Fazekas score. CTP-predicted nonviable tissue was defined as relative CBF <30%, and final infarct volume was quantified in DWI. We estimated mean MTT, CBV, and CBF in the asymptomatic hemisphere. In patients achieving complete reperfusion, we assessed the accuracy of nonviable tissue to predict final infarct volume using the intraclass correlation coefficient across periventricular hyperintensity/hypodensity Fazekas scores and variable relative CBF cutoffs.

RESULTS: MTT was longer (Spearman $\rho = 0.279$, $P < .001$) and CBF was lower ($\rho = -0.263$, $P < .001$) as the periventricular hyperintensity Fazekas score increased, while CBV was similar across groups ($\rho = -0.043$, $P = .513$). In the subgroup of patients achieving complete reperfusion, nonviable tissue—final infarct volume reliability was excellent in patients with periventricular hyperintensity Fazekas score grade 0 (intraclass correlation coefficient, 0.900; 95% CI, 0.805–0.950), fair in patients with periventricular hyperintensity Fazekas scores 1 (intraclass correlation coefficient, 0.569; 95% CI, 0.327–0.741) and 2 (intraclass correlation coefficient, 0.444; 95% CI, 0.165–0.657), and poor in patients with periventricular hyperintensity Fazekas score 3 (intraclass correlation coefficient, 0.310; 95% CI, −0.359–0.769). The most accurate cutoffs were relative CBF <30% for periventricular hyperintensity Fazekas score grades 0 and 1, relative CBF <25% for periventricular hyperintensity Fazekas score 2, and relative CBF <20% for periventricular hyperintensity Fazekas score 3. The reliability analysis according to periventricular hypodensity Fazekas score grades on NCCT was similar to that in follow-up MR imaging.

CONCLUSIONS: In patients with stroke, the presence of leukoaraiosis confounds the interpretation of CTP despite proper adjustment of CBF thresholds.

ABBREVIATIONS: FIV = final infarct volume; ICC = intraclass correlation coefficient; IQR = interquartile range; MT = mechanical thrombectomy; NVT = nonviable tissue; PVH = periventricular hyperintensity/hypodensity Fazekas score; rCBF = relative CBF

The main utility of perfusion images obtained from patients with acute ischemic stroke is the identification and quantification of areas of nonviable tissue (NVT) and areas of ischemic penumbra that represent hypoperfused but still salvageable tissue.1,2 These focal alterations in patients eligible for acute stroke therapies can be evaluated by dynamic contrast-enhanced CT and MR imaging acquisitions,3,4 the former being the most commonly used technique worldwide for the assessment of cerebral perfusion in patients with acute stroke.5 However, a great variability in the utility of perfusion imaging obtained from patients with acute ischemic stroke is the identification and quantification of areas of nonviable tissue (NVT) and areas of ischemic penumbra that represent hypoperfused but still salvageable tissue.1,2 These focal alterations in patients eligible for acute stroke therapies can be evaluated by dynamic contrast-enhanced CT and MR imaging acquisitions,3,4 the former being the most commonly used technique worldwide for the assessment of cerebral perfusion in patients with acute stroke.5 However, a great variability in the utility of perfusion imaging obtained from patients with acute ischemic stroke is the identification and quantification of areas of nonviable tissue (NVT) and areas of ischemic penumbra that represent hypoperfused but still salvageable tissue.1,2 These focal alterations in patients eligible for acute stroke therapies can be evaluated by dynamic contrast-enhanced CT and MR imaging acquisitions,3,4 the former being the most commonly used technique worldwide for the assessment of cerebral perfusion in patients with acute stroke.5 However, a great variability...
exists not only in image acquisition and postprocessing techniques but also in intrinsic features of cerebral perfusion. It is in fact, in physiologic conditions and in acute focal ischemia, brain perfusion is not the same in all its areas because it depends on the neuronal activity of different regions, where perfusion patterns may be different in patients with similar sites of occlusion and times from stroke onset to imaging acquisition. This variability in perfusion features may depend mostly on the efficiency of intrinsic compensatory mechanisms such as the collateral blood supply or vasodilation and oxygen extraction at capillary levels. Moreover, brain perfusion might also depend on the extent of leukoaraiosis, which is an age-related pathologic process strongly associated with cardiovascular risk factors and stroke. A recent study conducted on a large cohort of patients with acute stroke showed that hypoperfusion in the periventricular areas was related to the grade of leukoaraiosis, but a quantitative analysis was not assessed.

Therefore, leukoaraiosis may be associated with hypoperfusion and may cause an overestimation of the NVT in ischemic stroke, confounding the interpretation of CTP in patients eligible for reperfusion therapy. In this study, we aimed to quantify the cerebral perfusion parameters according to the grade of leukoaraiosis in a cohort of patients with large-vessel stroke treated with mechanical thrombectomy and to assess the accuracy of the estimation of infarct core based on variable CBF thresholds.

MATERIALS AND METHODS

Patients

This is a retrospective single-center study of 236 patients with large-vessel ischemic stroke in the anterior circulation treated with MT within 3.9 hours (interquartile range [IQR], 2.6–6.0 hours) from stroke onset who had pretreatment multimodal CT imaging and brain MR imaging at follow-up from March 2010 to December 2017 (Fig 1). Reperfusion after MT was quantified with the modified TICI scale.

The local Clinical Research Ethics Committee from the Hospital Clinic of Barcelona approved the study protocol (HCB/2019/0077) under the requirements of Spanish legislation in the field of biomedical research, the regulation (European Union) 2016/679 of the European Parliament and of the Council of April 27, 2016 on the protection of persons with regard to the processing of personal data and on the free movement of such data, the standards of Good Clinical Practice, as well as with the Helsinki Declaration of 1975 and 1983. Patient consent was not required due to the retrospective nature of the study design.

Neuroimaging Techniques

Multimodal imaging included, on admission, an NCCT, an angio-CT of the cerebral and intracranial arteries, and a CTP. CTP was performed within a median of 166 minutes (IQR, 88–265 minutes) of stroke onset who had pretreatment multimodal CT imaging and brain MR imaging at follow-up from March 2010 to December 2017 (Fig 1). Reperfusion after MT was quantified with the modified TICI scale.

The local Clinical Research Ethics Committee from the Hospital Clinic of Barcelona approved the study protocol (HCB/2019/0077) under the requirements of Spanish legislation in the field of biomedical research, the regulation (European Union) 2016/679 of the European Parliament and of the Council of April 27, 2016 on the protection of persons with regard to the processing of personal data and on the free movement of such data, the standards of Good Clinical Practice, as well as with the Helsinki Declaration of 1975 and 1983. Patient consent was not required due to the retrospective nature of the study design.

Neuroimaging Analysis in the Whole Cohort

Analyzing independently NCCT and FLAIR MR imaging sequences, 1 trained investigator (S.R.) used the Fazekas scale to calculate the extent of leukoaraiosis in the asymptomatic hemisphere only, thus avoiding the confounding effect of acute ischemic lesions. According to the neuroimaging technique, white matter changes were evaluated as periventricular hyperintensities on MR imaging and periventricular hypodensities on NCCT (periventricular hyperintensity/hypodensity Fazekas score [PVH]). In accordance with this scale, grade 0 defined the absence of white matter changes, grade 1 included caps or pencil-thin lining, grade 2 defined a smooth halo, and
grade 3 defined irregular periventricular lesions extending into the deep white matter.

**Neuroimaging Analysis in Patients with Complete Reperfusion**

The relationship between the grade of leukoaraiosis and the FIV was analyzed only in patients with complete reperfusion after MT (modified TICI 3) to reduce the confounding effect of variable infarct growth in patients with incomplete reperfusion after MT. In this subgroup, we assessed the intraclass correlation coefficient (ICC) and the volumetric bias between the NVT and the FIV according to the PVH on MR imaging and also explored ICC values across different rCBF thresholds (rCBF <30%, 25%, 20%, and 15%). Then, to assess the usefulness of evaluating the grade of leukoaraiosis on the pretreatment imaging, the same reliability analyses were conducted using the subgroups based on the NCCT-derived PVHs. Finally, to assess the internal validity of the study, we repeated the main imaging analysis in patients with complete reperfusion using a different software package (syngo.via CT Neuro Perfusion VB30; Siemens). We calculated the ICC and the volumetric bias according to the PVH on MR imaging and different rCBF thresholds (rCBF <30% and 20%).

**Statistics**

Categoric variables were compared using the χ² test if suitable, and alternatively using the Fisher exact test. Continuous variables with normal distribution were described by mean and SD, while continuous variables without normal distribution and ordinal variables were described by median and IQR. Means between 2 groups were compared using the Student t test, and medians between 2 groups were compared using the Mann-Whitney U or Kruskal-Wallis test as appropriate. The agreement between MR imaging and NCCT PVHs was evaluated with a linear-weighted κ statistic. The relationship between the MTT, CBV, and MTT values in the asymptomatic hemisphere with the Fazekas score was evaluated using the Spearman ρ correlation coefficient. The ICC was interpreted as previously described (ICC < 0.4, poor reliability; ICC, 0.4–0.75, from fair-to-good reliability; ICC > 0.75, excellent reliability). Volumetric bias was defined as the difference between the predicted and final infarct (NVT-FIV) across PVH groups. All statistical analyses were performed using SPSS 23.0 (IBM, Armonk, New York). We considered as statistically significant P values < .05, and all hypotheses were 2-sided.

**RESULTS**

**Leukoaraiosis and Hemodynamic Correlates in the Whole Population**

The main demographic, clinical, and radiologic features of the whole study cohort (n = 236) and of patients with complete reperfusion at the end of MT (n = 127) are shown in Table 1. PVHs of the whole cohort evaluated on posttreatment MR imaging and pretreatment NCCT are shown in Fig 2. Overall, the agreement

![FIG 2. PVHs on MR imaging and noncontrast CT.](image-url)
between the evaluations on MR imaging and NCCT was good ($\kappa = 0.69; \text{95\% CI, } 0.62–0.76$). Higher PVHs were associated with longer MTT (Spearman $\rho = 0.279, P < .001$) and lower CBF ($\rho = -0.263, P < .001$) but were not correlated with CBV values ($\rho = -0.043, P = .513$), as shown in Fig 3 and On-line Table 1. There was no correlation between CBF, CBV, and MTT values in the asymptomatic hemisphere and NVT ($P = .573, P = .251$, and $P = .978$, respectively) or FIV ($P = .902, P = .207$, and $P = .522$, respectively). NVT was similar in patients with different grades of PVH was less strong for rCBF <25% ($\rho = -0.153, P = .002$) and rCBF <20% ($\rho = -0.129, P = .01$) thresholds compared with the rCBF <30% threshold, while no significant correlation was found for the rCBF 15% threshold ($\rho = -0.074, P = .139$). Complete data of this analysis are shown in the On-line Table 2. Of note, the distribution of collateral scores and time to recanalization was not different among PVH categories as shown in On-line Table 3.

In the comparative analysis of different commercial software reperfusion ($P = .657$), but the FIV was inversely related to TICI subgroups ($\rho = -0.450, P < .001$).

**CTP Prediction of FIV in Relation to the Extent of Leukoaraiosis in Patients with Complete Reperfusion after MT**

In patients with complete reperfusion at the end of MT ($n = 127$), the agreement between NVT and FIV using the rCBF <30% cutoff was inversely correlated with PVH ($\rho = -0.199, P < .001$); ICC was excellent (ICC, 0.900; 95\% CI, 0.805–0.950) for patients with PVH 0 graded on MR imaging, remained fair for patients with PVH 1 (ICC, 0.569; 95\% CI, 0.327–0.741) and PVH 2 (ICC, 0.444; 95\% CI, 0.165–0.657), and was poor for patients with PVH 3 (ICC, 0.310; 95\% CI, -0.359–0.769). The analysis of CTP prediction of the FIV based on the NCCT PVH evaluation showed results similar to those of the MR imaging–based analysis as shown in Fig 4 and in On-line Table 2. Median volumetric bias was similar among MR imaging–derived PVH subgroups regardless of the technique used to grade leukoaraiosis (Table 2). Two representative cases illustrating these observations are shown in Fig 5.

A comprehensive threshold-finding analysis across different CTP-derived rCBF cutoffs was implemented to evaluate whether the extent of leukoaraiosis affected the prediction of FIV. In this exploratory analysis, the rCBF <30% threshold showed the highest ICC between NVT and FIV in patients with PVHs 0 and 1, whereas the rCBF <25% and rCBF <20% thresholds had a higher ICC than rCBF <30% for patients with PVHs 2 and 3, regardless of the neuroimaging technique used for the evaluation of leukoaraiosis (Fig 4). The rCBF <15% cutoff was less reliable for each grade of leukoaraiosis. The correlation between NVT-FIV ICC and

**FIG 3.** Boxplot analysis of CTP maps in the asymptomatic hemisphere according to the PVH score on MR imaging in the whole population ($N = 236$).

**FIG 4.** ICC analysis of the predicted final infarct volume on CTP according to different rCBF cutoffs and the grade of leukoaraiosis assessed by the PVH on follow-up MR imaging and on pretreatment NCCT in the subgroup of patients with complete reperfusion after mechanical thrombectomy ($n = 127$). Of note, the agreement in patients without leukoaraiosis was excellent for rCBF <30% and rCBF <25% cutoffs and remained good for rCBF <20% and rCBF <15%. In patients with leukoaraiosis, across increasing PVHs, the overall reliability of CTP decreased and more restrictive thresholds (mostly rCBF <25% and rCBF <20%) had better agreement than the commonly used rCBF <30%.
packages, the agreement of NVT estimation using the rCBF <30% threshold between MIstar and syngo.via software was good (ICC, 0.664; 95% CI, 0.469–0.782). A representative example is shown in the On-line Figure. With syngo.via, there was still an inverse correlation with PVHs for both rCBF <30% ($\rho = -0.275$, $P < .001$) and rCBF <20% ($\rho = -0.119$, $P = .018$). The rCBF <20% cutoff showed a higher ICC compared with rCBF <30% in patients with PVH >0 as shown in On-line Table 4.

**DISCUSSION**

In this study, we investigated whether the presence and severity of leukoaraiosis confounded the interpretation of CTP findings for the prediction of final infarct volume in patients with complete reperfusion following MT. The main result of the study was that the extent of leukoaraiosis altered the prediction of final infarct volume following MT but was not correlated to overestimation of the final infarct volume. Although the use of more restrictive rCBF thresholds may improve the estimation of tissue viability in patients with a high grade of leukoaraiosis, the accuracy of CTP was reduced in these patients. Finally, the study also found that NCCT was a reliable imaging technique to identify those patients whose extent of leukoaraiosis could compromise the accuracy of CTP interpretation.

The estimation of infarct core by means of a relative CBF threshold lower than 30% (rCBF <30%) is broadly accepted to define NVT in acute stroke. In our study, the reliability of the rCBF <30% threshold decreased in relation to an increased
prominence of leukoaraiosis. Thus, the rCBF <30% threshold was only excellent for the prediction of FIV in patients without leukoaraiosis (PVH 0). Conversely, in patients with mild (PVH 1) and moderate (PVH 2) leukoaraiosis, the application of that threshold had a lower but still fair grade of agreement between CTP-derived NVT and the FIV on follow-up MR imaging, while tissue-viability prediction was only seriously hampered in patients with a severe grade of leukoaraiosis (PVH 3). According to these results, the rCBF <30% cutoff remained the most reliable in patients with PVHs 0 and 1. However, in patients with higher grades of leukoaraiosis, the prediction of tissue viability was only moderate, even after applying more restrictive thresholds (rCBF <25% or rCBF <20% cutoffs). Therefore, the burden of leukoaraiosis did not reflect overestimation of the infarct core despite an insignificant tendency for higher volumetric bias in the PVH 3 subgroup, and the worse FIV prediction might also depend on other factors that may affect hemodynamic measures in patients with small-vessel disease, such as blood-brain barrier permeability derangements,21,22 collateral circulation status,23 and cerebrovascular reactivity.24,25

In agreement with previous studies, the evaluation of periventricular leukoaraiosis on NCCT scans showed a good grade of agreement with the evaluation of the Fazekas scale on MR imaging.26–27 Accordingly, our study supports the use of NCCT to quantify the grade of leukoaraiosis and thus to improve the accuracy of the interpretation of CTP maps in potential candidates for endovascular therapy, especially in extended time windows in which the presence of severely hypoperfused areas might preclude the use of reperfusion therapy according to recent randomized clinical trials.28–30 Although perfusion imaging adds useful data about tissue viability in stroke assessment, our results highlighted the limitations of CTP in the prediction of final infarct, and support the current stroke guideline indications based on NCCT ASPECTS evaluation for endovascular therapies in the first 6-hour window, while perfusion imaging is required only in extended time windows. Further studies are warranted to assess the role of leukoaraiosis on the accuracy of CTP maps in patients with stroke imaged in late time windows.

The main results of this study were confirmed by using alternative commercial software packages. Despite small differences related to optimal thresholds according to the software used,11 the accuracy of final infarct prediction was still inversely related to the grade of leukoaraiosis, and the more restrictive rCBF <20% cutoffs were shown to be more suitable in patients with a high-grade of white matter hyperintensities as well.

This study has some limitations. First, the time from CTP to follow-up MR imaging may affect the accuracy of the FIV prediction due to possible dynamic alterations in the DWI intensity.32 However, our cohort was rather homogeneous because most patients had undergone MR imaging within 48 hours from MT. Second, the low prevalence of patients with PVH 3 in this cohort and the lack of a specific assessment of perfusion parameters in the white matter and the mirror region of the final infarct could have underpowered the analysis of CTP maps. Nevertheless, this cohort study represented faithfully the population eligible for stroke endovascular therapy at our center, and these findings may thus be valid for regular use in clinical practice.

CONCLUSIONS

The extent of leukoaraiosis in patients with acute stroke eligible for MT impairs the accuracy of CTP maps for the prediction of tissue viability, even despite appropriate adjustment of CBF cutoffs. Therefore, the variable prevalence of leukoaraiosis in this clinical setting should be accounted for at the time of the perfusion study evaluation. Further studies assessing the characteristics of white matter hemodynamics in acute stroke are required to provide further insight into the efficacy of reperfusion therapies in patients with this condition.
