COVID-19 Neurologic Complication with CNS Vasculitis-Like Pattern

ABSTRACT
SUMMARY: Coronavirus disease 2019 (COVID-19) is a viral infection caused by the Severe Acute Respiratory Syndrome coronavirus 2 (SARS-CoV-2), which spreads rapidly from person to person and manifests in most symptomatic patients as a respiratory illness, similar to prior SARS viruses. Neurologic manifestations of COVID-19 are uncommon; those so far reported include encephalopathy, stroke from large-vessel occlusion, and polyneuropathy. We report a unique neurologic complication of COVID-19 in a patient who had extensive cerebral small-vessel ischemic lesions resembling cerebral vasculitis in a characteristic combined imaging pattern of ischemia, hemorrhage, and punctuate postcontrast enhancement. Also, a characteristic lower extremity skin rash was present in our patient. Our observation lends support to the increasingly suspected mechanism of “endotheliitis” associated with this novel coronavirus.

ABBREVIATIONS: ACE2 = angiotensin converting enzyme 2; COVID-19 = coronavirus disease 2019; SARS-CoV-2 = Severe Acute Respiratory Syndrome coronavirus 2

Coronavirus disease 2019 (COVID-19) has now spread to the whole world following an outbreak in China in late 2019.1 The virus is so highly contagious that the World Health Organization has declared COVID-19 a pandemic, with close to 3.5 million confirmed cases and 250,000 fatalities worldwide at the time of this report (May 1, 2020).1,2 Similar to other coronaviruses, the Severe Acute Respiratory Syndrome coronavirus 2 (SARS-CoV-2) virus primarily targets the respiratory system. In symptomatic patients, the most common symptoms are fever, fatigue, cough, headache, and shortness of breath. Severely symptomatic patients may present with pneumonia, acute respiratory distress syndrome, acute cardiac dysfunction from myocarditis, and multiorgan failure.3-5 Several mild neurologic manifestations of COVID-19 have now been reported, which include hyposmia or anosmia.6-8 More severe neurologic complications have also been recently reported, which may possibly be associated with COVID-19, including acute hemorrhagic necrotizing encephalopathy,9 acute transverse myelitis and Guillain Barré syndrome,10 and meningitis.11 We report herein a unique neurologic complication of COVID-19 with extensive ischemic lesions resembling CNS vasculitis.

Case Report
A 65-year-old man presented to the emergency department with a 5-day history of fatigue, fever, and cough. Initial blood work showed an inflammatory syndrome with an elevated C-reactive protein (60 mg/L), bicytopenia (normocytic anemia and thrombocytopenia), and lymphopenia.3-5 Because oxygen saturation continued to drop to 88%, with worsening of skin rash and tachypnea, the patient was admitted to the pulmonary intensive care unit.
Rapid stabilization of pulmonary function was obtained with oxygen and care in the intensive care unit; however, the patient remained drowsy and unarousable despite discontinuation of sedation. CT and MR imaging of the brain were performed to look for possible neurologic complications such as hypoxic-ischemic injuries or encephalitis. CT showed multiple white matter, basal ganglia, and cerebellar hypodensities and bilateral globus pallidus hyperdensities (Fig 1), suggestive of hemorrhage confirmed on T2*-weighted MR imaging (Fig 2).

Brain MR imaging showed extensive ischemic lesions with restricted diffusion (Fig 3), involving the centrum semiovale, corpus callosum, basal ganglia, and cerebellum (Fig 4), with patchy/punctuate enhancement (Fig 5). Coronal 3D reconstruction MRA of supra-aortic arteries showed no detectable abnormality of large intra- or extracranial vessels (Fig 6).

**DISCUSSION**

Neurologic complications are definitely associated with COVID-19, though the mechanism of neurologic injury remains speculative. Encephalopathy, ischemic stroke from large-vessel occlusion, Guillain-Barré syndrome, and reversible cranial nerve injuries (Miller Fisher syndrome) have all been reported with no evidence thus far that the SARS-CoV-2 can cross the blood-brain barrier.

In our patient, hypoxic-ischemic injury was considered an unlikely mechanism of injury because the patient had remained responsive throughout the period of low oxygen saturation, and only deteriorated several hours after successful stabilization of oxygen saturation; in addition, the patient did not have cardiac arrest. Also, imaging studies showed sparing of the striatum and cortical structures throughout.
Similarly, a pro-thrombotic state was not considered a likely causative factor because thorough coagulation panel findings (including the anti-phospholipid antigen) were normal.

Neuroimaging findings in our patient suggest the possibility of injury to the small intracranial vasculature in the distribution of distal perforating arteries. The association of ischemic and hemorrhagic lesions to the “patchy/punctate” enhancement pattern is highly suggestive of vasculitis. The punctate enhancement pattern has been reported to be characteristic of disease processes that progress from endoluminal (angiocentric lymphoma), vessel wall (vasculitis), or perivascular (progressive multifocal leukoencephalopathy) cellular proliferation.

SARS-CoV-2 infects the host through its CoV spike glycoprotein, which binds to the angiotensin converting enzyme 2 (ACE2) receptor, which is expressed in the lungs, heart, and kidney (the most frequently targeted organs in COVID-19), but also endothelial cells. Endothelial cell involvement with COVID-19 has recently been demonstrated across vascular beds. The expression of the ACE2 receptor in neurons and cerebral endothelial cells indicates a high level of invasiveness for the SARS-CoV-2 in comparison with other coronaviruses (SARS and Middle East Respiratory Syndrome). Such an endothelial mechanism of injury (endotheliitis) has been convincingly demonstrated in severe cases of cardiac injury in humans. Histologic evidence of COVID-19–induced vasculitis has also been reported in several other organs including the lung, liver, kidney, or skin. The concomitance of a characteristic skin rash with a “mottled” appearance and such a pattern of CNS lesions in our patient would lend support to a mechanism of virus-related endothelial injury.

CONCLUSIONS
COVID-19–related neurologic complications remain poorly understood. We report a patient whose clinical presentation and neuroimaging findings

FIG 4. Diffuse ischemic lesions on FLAIR imaging. Axial (A–C) and coronal (D) FLAIR images show hyperintense ischemic lesions within the periventricular white matter, basal ganglia, cerebellar peduncles (white arrows), and the corpus callosum (A, red arrow).

FIG 5. Patchy/punctate postcontrast enhancement pattern with consistent small vessel involvement. Postcontrast T1 MR imaging shows intense patchy enhancement of all lesions, in particular the globus pallidus bilaterally (A, white arrows), with a punctate pattern in the middle cerebellar peduncles and cerebellar hemispheres (B, arrow).
are supportive of a mechanism of SARS-CoV-2–induced vasculitis/endotheliitis.

ACKNOWLEDGMENTS
The authors wish to acknowledge Fanny Ducourneau, radiologic technologist, and Gilles Boulu, radiologist, who kindly agreed to perform the MR imaging study in our patient.
